## 3DEXPERIENCE

# can help people who have a damaged skeleton, could they walk again?

A robotic skeleton  
– a dream our software could bring to life.

How long before bionic humans are fact, not science fiction? With the development of sophisticated new exoskeletons, designed to help paralyzed people walk again, those days are not such a distant future.

Such engineering innovations are made possible by the **3DEXPERIENCE** software platform from Dassault Systèmes. Across all industries, teams of mechanical, software and electronic engineers collaborate on complex, high-tech projects – and get them right the first time. **3DEXPERIENCE** helps us think not just about improving the quality of life of the severely injured, but also about innovations that will put them back on their feet.

### Our software applications for the 3DEXPERIENCE Platform:

CATIA / SOLIDWORKS / SIMULIA / DELMIA / ENOVIA  
GEOVIA / EXALEAD / NETVIBES / 3DSW4M / 3DVIA

It takes a special kind of compass to explore the world's future possibilities. Innovative companies use our **3DEXPERIENCE** software platform to understand the present and navigate the future.

[SPECTRUM.IEEE.ORG](http://SPECTRUM.IEEE.ORG) AVAILABLE 1 SEPTEMBER**A Robot Ankle for Amputees**

The BiOM is one of the world's most advanced prosthetics. Created by iWalk, this robotic ankle can tell whether the user is walking, running, climbing a ramp, or walking down stairs. Its sensors measure where it is in space, and its microprocessors determine how much it should flex and how hard it should push off from the ground in order to produce a natural gait. It's a smart, self-powered prosthetic, and a huge stride forward in bionics.

[THEINSTITUTE.IEEE.ORG](http://THEINSTITUTE.IEEE.ORG) AVAILABLE 7 SEPTEMBER**WORKING WITH SKETCHY IMAGES**

Television shows like "CSI: Crime Scene Investigation" feature high-tech computer systems that can easily identify suspects. But the face-matching technology of real-life law-enforcement agencies is not yet that sophisticated. In this issue, read about how several IEEE members at Michigan State University, in East Lansing, are working to make matching forensic sketches to mug shots a reality.

**IEEE XPLORE IS NOW EASIER TO USE**

The new IEEE Business Platform, which includes enhancements to IEEE Xplore, was launched this year. *The Institute* takes a look at the new features as well as what to expect in the future.

**IEEE MEMBERS: AN IN-DEPTH LOOK**

Why do people join and remain members of IEEE? Learn the answer by reading the results of the IEEE Member Segmentation Survey. Conducted every four years, the survey is designed to gauge members' satisfaction with IEEE's products and services.

## back story

## DIY Publishing

IT'S NO SECRET that publishing is going through its greatest upheaval since the industrialization of printing presses in the 19th century. Electronic books and print-on-demand services now allow anyone with the know-how to reach millions of potential readers without securing publishing's traditional go-ahead: the backing of a publishing house.

But getting that know-how can be a challenge. So for this issue, we asked the husband-and-wife team of Daniel and Sally Wiener Grotta to walk prospective authors through the technical details of taking a book from a word processor to selling it online (see "Hands On: Publishing Yourself").

For the Grottas, the shift to digital publishing came as no surprise: In 1967, Daniel attended the Publishing Procedures course at Radcliffe College, then the only academic program in publishing in the United States. He recalls discussions about "having automatic fax machines that would send readers pages, or having text displayed on a television-like tablet, like the ones they had on 'Star Trek.'"

The Grottas are quick to point out that it's not just technology that's driving authors toward digital publishing. Publishing houses themselves sped along the exodus by alienating writers. The old guard of "gentleman publishers" were bought out by financiers "who didn't invest

in their inventory, didn't invest in authors, but wanted content they could roll over quickly," says Sally. "Publishers no longer had loyalty to their authors, so authors stopped feeling loyal to publishers."

The Grottas have published several books in the traditional way, including the first biography of J.R.R. Tolkien (by Daniel), but have now moved to digital publishing. They believe that the notion of a publishing house still has one important thing to offer in the digital age: a stamp

of approval, allowing readers to find books they are likely to enjoy amid a flood of titles. However, the Grottas think that the future of these houses lies in boutique operations that offer specialized content and greater support for writers. To that end, they have recently founded their own digital imprint, Pixel Hall Press. It will concentrate on character-driven adult and young adult fiction, and art and photography nonfiction. □

## CITING ARTICLES IN IEEE SPECTRUM

IEEE Spectrum publishes two editions. In the international edition, the abbreviation INT appears at the foot of each page. The North American edition is identified with the letters NA. Both have the same editorial content, but because of differences in advertising, page numbers may differ. In citations, you should include the issue designation. For example, The Data is in *IEEE Spectrum*, Vol. 49, no. 9 (INT), September 2012, p. 56, or in *IEEE Spectrum*, Vol. 49, no. 9 (NA), September 2012, p. 72.

# contributors

**CARTER M. ARMSTRONG**  
is vice president of engineering in the electron devices

division of L-3 Communications, in San Carlos, Calif. In "The Truth About Terahertz" [p. 28], he discusses the promise and perils of trying to exploit this region of the electromagnetic spectrum. A vacuum-device scientist, he says one of his favorite *IEEE Spectrum* articles is Robert S. Symons's "Tubes: Still Vital After All These Years," in the April 1998 issue. "It was true then, and it's still true today," Armstrong says.

**STEVEN J. FRANK**  
is a graduate of Harvard Law School and a partner at Boston's Bingham McCutchen. He writes in this issue about his experience taking MIT's large-scale remote-learning course in circuit design [p. 21]. Although he knew something about the subject, "the level of challenge was, shall we say, a bit unexpected. But so were the rewards." Frank is the author of *Intellectual Property for Investors and Technology Managers* (Cambridge University Press, 2006).

**ALFRED POOR**  
writes in "Reformulating Displays" [p. 22] about new materials

coming soon to big-screen televisions. A senior member of the Society for Information Display, Poor also reported on displays in *Spectrum's* July issue, where he covered the ongoing shift to smart TV. At *PC Magazine*, Poor was a contributing editor for more than 20 years and the publication's first lead analyst for business displays.

**DAN SIEWIOREK**  
is a professor at Carnegie Mellon University. He is also director of the

Quality of Life Technology Center, which is run jointly by CMU and the University of Pittsburgh and sponsored by the National Science Foundation. He is developing virtual-coaching applications for smartphones—precursors, he hopes, of the ones he describes in "Generation Smartphone" [p. 46]. While his two daughters were growing up, he fantasized about apps like these, which might have saved him much consternation.

**RICHARD STEVENSON**  
returns to photo-voltaic cells in "Tapping the Power of 100 Suns" [p. 40], a topic he last covered for *Spectrum* in 2008. This time he looks not at the immediate commercial possibilities but rather at an effort funded by the U.S. Defense Advanced Research Projects Agency to drastically increase the efficiency of PV modules that soldiers might carry into the field. His Ph.D. in physics from the University of Cambridge centered on the compound semiconductors used in such PVs.

**EMILY WALTZ**,  
a freelance journalist based in Nashville, frequently writes for *Nature* and

*Nature Biotechnology*. For "How I Quantified Myself" [p. 34], she spent two months trying out various health-, fitness-, and sleep-monitoring gadgets that recorded her biological statistics. She says her tennis buddies were enthusiastic about the experiment and quizzed her after games on how many calories they'd burned and how many steps they'd taken.

# CST STUDIO SUITE 2012

Discover what happens...

## Making Sense of the Real World – System Level EM Simulation

Simulation of cancer treatment  
by RF thermoablation

Components don't exist in electromagnetic isolation. They influence their neighbors' performance. They are affected by the enclosure or structure around them. They are susceptible to outside influences. With System Assembly and Modeling, CST STUDIO SUITE 2012 helps optimize component as well as system performance.

Involved in biomedical applications? You can read about how CST technology was used to simulate biomedical devices at [www.cst.com/biomed](http://www.cst.com/biomed).

If you're more interested in filters, couplers, planar and multilayer structures, we've a wide variety of worked application examples live on our website at [www.cst.com/apps](http://www.cst.com/apps).

Get the big picture of what's really going on. Ensure your product and components perform in the toughest of environments.

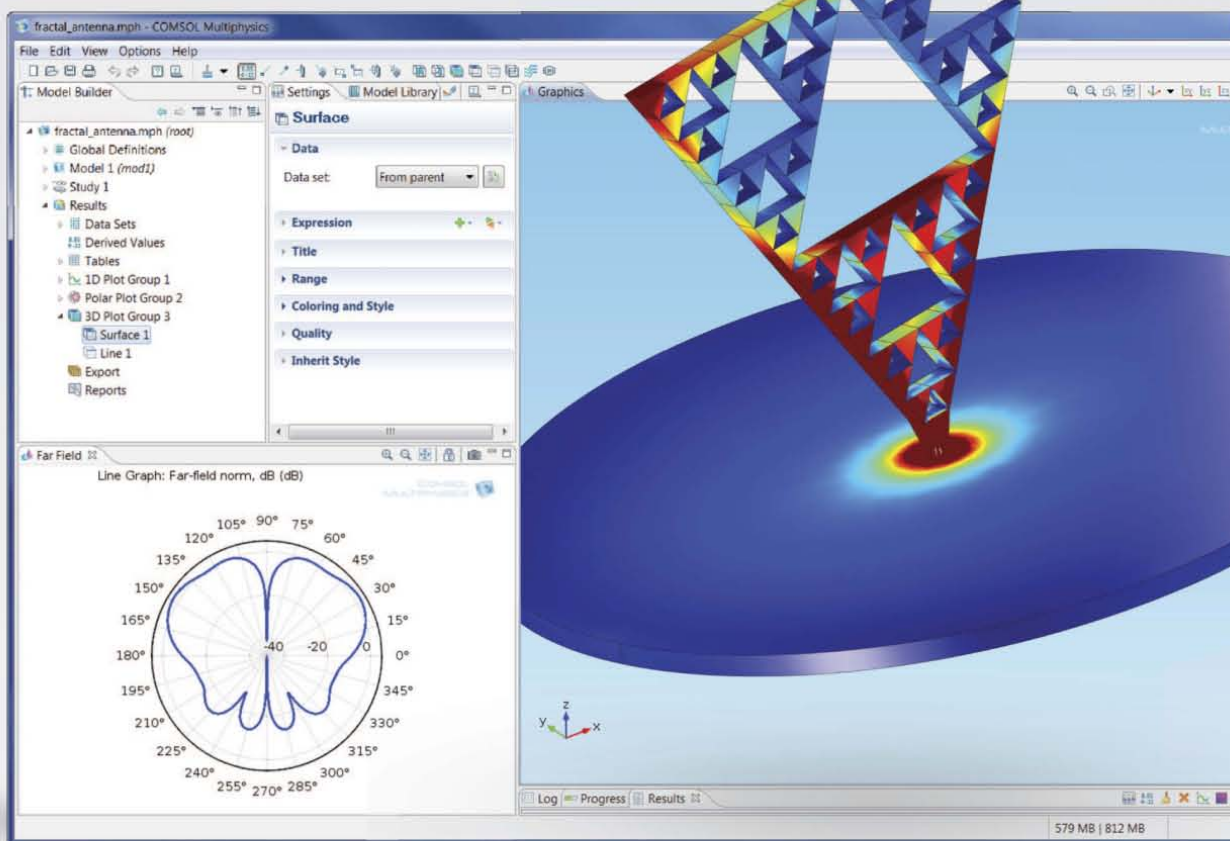

Choose CST STUDIO SUITE 2012 – complete technology for 3D EM.

CHANGING THE STANDARDS

# Verify and optimize COMSOL M

**ANTENNAS:** The Sierpinski fractal monopole antenna shows multiband responses inherited from the nature of a fractal structure. Results show the magnitude of the electric field on the surface of the structure as well the far field radiation pattern.

COMSOL  
CONFERENCE  
BOSTON

## Our Smartphones, Ourselves

WHEN MY family goes on a long drive, we take our US \$79 Garmin GPS locator along to help us out. It talks to us in what sounds like a female British voice, and so we talk to her, and about her, along the way. Allison (as we call her) usually seems to want to take the scenic route. She wants to turn around. She says to take exit 44, not 42. She recalculates. We also carry a map to validate her directions. Happily enough, she never complains about our second-guessing. Having turned “it” into “she,” we feel a little guilty when we ignore her advice. We also tell her when we’re stopping for gas and even thank her for a job well done.

So just imagine what will happen when smartphones get really smart—like the devices described in Dan Siewiorek’s “Generation Smartphone.” Siewiorek tells the story of Tom, a man from the future, who is accompanied throughout his life’s journey by a series of “SmartPhone 2x.Os.” Each acts as a surrogate guardian, personal assistant, teacher, life coach, and companion, presumably vigilant and loyal to the very end—or at least until it’s replaced by the next version.

We’d certainly be drawn to such a thing in my home. We’re already overly attached to the vibrating, marimba-chiming boxes we carry around the clock.

Today’s smartphones are remarkable pieces of technology, but they have only just begun to communicate with us naturally, using voice interfaces like the iPhone’s Siri.

But outside of a few specific areas—dining, calendaring, and so on—let’s face it: Siri is still pretty clueless. Future generations of smartphones, however, will exploit much more powerful processors and software to “learn” about our environment and us. They’ll absorb vast amounts of data, much of it coming from sensors and the so-called Internet of Things that they will be immersed in.

Among the sensors feeding these future phones will be personal health and wellness devices, of the sort described in Emily Waltz’s article in this issue, “How I Quantified Myself.” They’ll monitor our sleep patterns, blood pressure, heart rate, and glucose levels. Naturally, we’ll want our phones to send this data to our physicians and compare them with our own baselines as well as medical databases.

But what happens when this brilliant smartphone of yours is able to evaluate your health data in real time and quickly give you diagnoses, exhortations, and admonitions in a Siri-like voice—with or without a British accent? Will you be more or less likely to take

seriously the advice of a phone, compared to that of a flesh-and-blood physician?

The potential quagmires posed by a souped-up Siri are not hard to imagine. Perhaps your phone will report health problems in such a way that they could be accessed by prospective employers, love interests, or insurance companies. Noticing your distractibility and device addiction while you text and drive, perhaps it will turn off your car and send one report to the police and one to your therapist. And when it makes mistakes—you weren’t

driving erratically, the phone’s accelerometer was on the fritz—rectifying the situation could prove tough.

Despite such caveats, a future of smartphone companions may be upon us before we know it. Silicon Valley venture capitalist Marc Andreessen predicts that just 10 years from now, 5 billion people will have smartphones like the ones that already rule many of our homes and offices. What will it mean for our cultures, our work, and our lives when all these smartphones are able to talk to us, and then to each other? —SUSAN HASSLER

## Argument Over the Value of Solar Focuses on Spain

Analysts disagree on whether the energy returned from solar is worth the energy invested

**O**IL PRODUCERS are working harder than ever to replace their reserves and, increasingly, turning to nonconventional petroleum sources such as Canada's tarry bitumen and ultra-deepwater offshore wells. As they do so, they are investing more energy to deliver each new barrel of oil. Similar trends are playing out for natural gas and coal, and a growing number of energy analysts are worried. They see these accelerating trends—what they call fossil fuels' declining

energy return on investment, or EROI—as an ill portent for the global economy.

The critical question for the future is whether renewable energy sources can fill the gap, sustaining the energy surplus that has supported explosive growth in human life span and population since the industrial revolution. A book due out later this year promises a hard-nosed look at solar energy—the fastest growing form of renewable energy—and is likely to raise plenty of eyebrows.

Coauthored by ecologist Charles A.S. Hall and Spanish telecom and solar systems engineer Pedro A. Prieto, the book is a case study of Spain's utility-scale installations of photovoltaics. It will be, the authors claim, the first comprehensive analysis of large-scale PV based on data rather than models. Hall—a professor at the State University of New York College of Environmental Science and Forestry, in Syracuse—formalized the concept of EROI more than 40 years ago, as the energy yielded by an energy-gathering activity divided by the energy invested in that activity.

While mum on their EROI numbers, Hall and Prieto say the book will demonstrate that building and operating PV requires considerably more energy than its promoters claim. And, they add, fossil fuels provide the bulk of the energy investment.

**SPANISH SOLAR:** Photovoltaics like these in Cuervo, Spain, are under scrutiny. New research suggests they produce too little energy.

# update

## Oil and Gas Are Taking More Energy to Extract

Energy return on investment, the amount of energy produced divided by the energy needed to acquire it, has been on the decline in the United States [above] and the rest of the world.

## Renewables Will Have a Hard Time Filling the Gap

Estimates of the energy return on investment for several energy sources vary widely, especially for renewables. (Shown are the mean estimate and standard deviation from a meta-analysis of many studies.)

"The conclusion is that solar PV systems are very much underpinned by a fossil fuel society," says Prieto.

Prieto cites two dozen energy inputs left out of many life-cycle analyses of photovoltaic systems. He witnessed these inputs directly while building one of Spain's earliest utility-scale solar facilities—a 1-megawatt plant in Extremadura that began operating in 2006—and while supporting subsequent PV installations.

The factors include construction of roads, water pipes, and transmission lines to serve the often-remote solar sites, and even international flights to get on-site help from specialist engineers.

All told, says Prieto, the result could be an EROI figure even lower than the already controversial EROI of 6.8 that Hall previously cited for PV, which would make it inferior to most other forms of power generation [see charts, above]. According to

Prieto we are "very far" from having solar power systems that provide substantial net energy to society, and he is not much more optimistic about similarly fast-growing wind power.

Not all energy analysts tracking EROI accept this dim view of renewable energy. For one thing, analyses of fossil fuels likely neglect to count many real-world energy inputs such as those that Prieto is adding to solar's baggage. For another, PV efficiency is rising fast. An updated analysis published this March by Marco Raugei, a life-cycle expert at Barcelona's Universitat Pompeu Fabra, and two U.S.-based colleagues calculates EROIs of 19 to 38 for various PV module types.

Joshua Pearce, an associate professor of materials science and engineering at Michigan Technological University, notes that energy policies could improve real returns from solar energy by offering incentives for the use of the highest-EROI systems. Centralized solar farms full of cheap crystalline silicon modules—which EROI studies show to be the most energy intensive of PV installations—dominate the market because they are the most profitable to build. A deployment scheme designed to reward EROI instead would shift the calculus, says Pearce: "Before a single centralized PV facility was erected, we would have thin-film

PV panels integrated into every appropriate rooftop."

Stanford University energy systems expert Adam Brandt, meanwhile, discounts PV's current reliance on fossil energy. What's important, he says, is that a PV installation can use fossil energy to produce carbon-free power—a critical response to climate change. "If you consume one unit of fossil fuel and get something like 8 or 12 units of solar energy out, that's a positive story," Brandt says.

If the optimists are wrong, however, prepare for a shock. In a 2009 paper, Hall and his colleagues estimated that energy supplies with an EROI of at least 12 to 13 were required to support the trappings of modern developed nations, such as higher education, technological progress, and high art. Oil and gas production in the United States may have already fallen below that threshold, the paper says, and global production appears to be following fast.

The implications, according to Prieto and Hall, are sobering. In fact, Prieto believes he is already witnessing economic decline caused, in part, by petroleum's dwindling EROI. He sees it manifested in Spain's debt crisis. "Energy is the ability to do work. If we do not have more energy one year than the preceding year, we will hardly be able to grow," he says. "And, if there is no growth, the financial system collapses." —PETER FAIRLEY

# "THE NORTHERN GRID HAS FAILED AGAIN."

## Tech Industry Money in U.S. Elections

With stakes low, so are campaign contributions

WHEN IT COMES to funding political campaigns, the technology industry maintains a pretty low profile. In fact, figures from the Center for Responsive Politics (CRP) show the industry is spending about the same amount as in previous presidential election years [see chart, "Contributions to U.S. Election Campaigns"]. That's despite overall campaign spending that's set to beat 2008's record by US \$400 million.

As of the end of July, numbers tallied by the CRP showed that contributors from the electronics and communications category (which includes computer and Internet companies) had spent \$94 million. Following historical giving patterns, that put the category on pace to match total 2008 spending of \$149 million. "Contributions tend to peak close to the election—that's when you typically see the most money flowing into the system," says Douglas H. Weber, a senior researcher at the CRP.

Ever since the watershed year of 2000, the end of a decade in which the Microsoft antitrust trial showed the tech industry that it needed to pay attention to Washington, Silicon Valley has been experimenting with ways of flexing its political muscle. Yet it still doesn't give nearly as much money as other industries, such as finance and banking, and legal.

Betsy Mullins, senior vice president for policy and political affairs at the tech industry advocacy group TechNet, says the industry is still in its adolescence

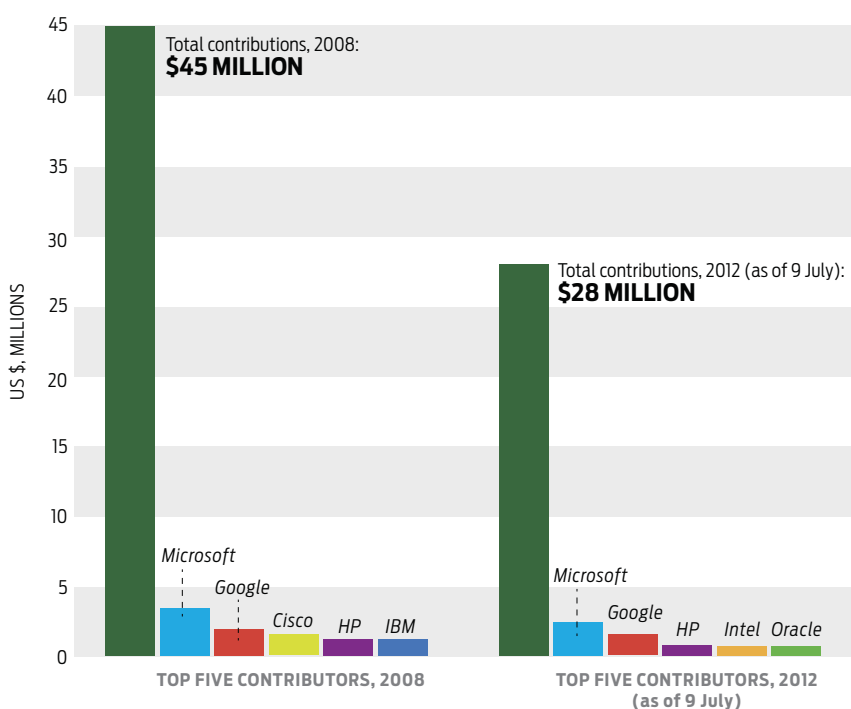

### Contributions to U.S. Election Campaigns

The **electronics and communications industry** is on track to match its 2008 spending

The **computer and Internet sector** contributes less than half of the tech industry's \$94 million

### Microsoft and Google look likely to be top campaign donors again

The **tech industry** is not among the biggest contributors for the current campaign

when it comes to political giving. “Over time, this unregulated industry gradually bumped into more issues and realized it needed stronger relationships in D.C.,” she says. Even though tech companies have risen in the Fortune 500 (Google is currently ranked 73), their political giving pales in comparison to some of their peers on that list, she says. “Banks and telecommunications companies have political giving and lobbying

down to an art form, because they’ve been doing it for 100 years,” she says.

At the same time, the shifting rules in campaign finance make it hard to be certain exactly how much the tech industry—or any industry—is giving and how. “Our suspicion is that there may be a lot of money that we’re not seeing, that’s following a different pattern,” says Bill Allison, editorial director at the government watchdog group Sunlight

Foundation. “But unfortunately we can’t say with any certainty because we just don’t know who the donors are.”

Those shifting rules have changed and will probably continue to change how companies give. “All of these variables are still shaking themselves out,” says Mullins. “I think in four years you’re going to see a very different type of political activity than what the tech community is doing today. I can’t predict what that’s going to be, but all these factors influence what tech does in the political space.”

Already, tech companies are exploring giving more than just money, such as offering free training. “Facebook and Twitter both have active efforts to recruit members of Congress to use their platforms to communicate with their constituents,” says Allison. “That’s not necessarily a campaign contribution or a lobbying campaign, but clearly it’s an attempt to both sell their services and to get members of Congress to have a good impression of them.”

—TAM HARBERT

## THE RICH AND THEIR REACTORS

Many countries are backing away from nuclear power, but some of the world’s most visible entrepreneurs are throwing their weight behind one version of the technology or another. Here are the nuclear ambitions of a triumvirate with a collective fortune of US \$83.6 billion. —Dave Levitan

### SIR RICHARD BRANSON

The Virgin Group chairman is known for some extravagant investments, perhaps most notably Virgin Galactic, which plans to send you—yes, *you*—into space. Branson recently sent a letter to U.S. president Barack Obama asking for a meeting and urging him to reopen government research into integral fast reactors (IFR), although he apparently has not yet thrown any money into the idea. Also known as fast breeders, IFRs can burn the waste uranium and plutonium generated by standard fission reactors, potentially solving the ongoing nuclear waste question and reducing the risk of nuclear weapons proliferation. Still, there is plenty of controversy surrounding these reactors—enough for Obama to decline the request.

### BILL GATES

The world’s second-richest person is actually spending some dough on nuclear power, as a significant investor in a company called TerraPower, based in Bellevue, Wash. The company is working on a design called a traveling-wave reactor (TWR). These reactors need a small amount of enriched uranium to start up, but once on line, they can sustain themselves using spent uranium from standard reactors. In a TWR, a slow-moving wave of neutrons converts adjacent waste products into fissile isotopes. It would, theoretically, require far less fuel and maintenance than today’s reactors. Gates has reportedly invested tens of millions of dollars.

### JEFF BEZOS

Amazon’s founder is throwing his money further into the reaches of science fiction than his cobillionaires. His investment company, Bezos Expeditions, contributed in 2011 some unknown portion of \$19.5 million raised by the Canadian company General Fusion. As the name suggests, General Fusion is going for the sun-in-a-bottle approach to nuclear power, focusing on a technique known as magnetized target fusion. It’s a hybrid of the magnetic fusion scientists are working on at ITER, in France, and the inertial confinement fusion research at the National Ignition Facility, in California. The Bezos-backed scheme may seem like pie in the sky, but... well, it probably is.

**83 MILLION** Number of illegitimate Facebook accounts. The social network says about half of these were just duplicate accounts, but it labeled 14 million accounts “undesirable.”

# Predicting the Future of Drought Prediction

Better instruments and models could help scientists forecast droughts years in advance

**A**S EXTREME WEATHER events go, droughts—like the one that singed Russia’s wheat crop two summers ago and the one that engulfed the United States in July—are about as tricky as it gets. Unlike hurricanes and tornadoes, drought does not have an obvious start or end. In fact, there isn’t even a clear definition for it, making it hard to measure and monitor, let alone predict. But with better observations of the earth, oceans, and atmosphere and improvements in computer modeling, scientists think they’ll be able to foresee the chances of drought up to a decade in advance, and better predict droughts that arise suddenly or last longer than a few months.

Today, scientists can forecast drought only about three months ahead for most parts of the world with any significant certainty.

“Forecasting drought is an inexact science,” says Brian Fuchs, a climatologist at the National Drought

Mitigation Center (NDMC) at the University of Nebraska–Lincoln. “Drought is typically characterized by slow onset and slow recovery. To pick up signals of something that happens over weeks or months is hard for computer models.”

Drought involves a seemingly inexhaustible list of factors—from local ones such as groundwater level, stream flow, soil moisture, and vegetation, to large-scale global weather patterns such as El Niño and La Niña. All of these change over different time periods, from days to decades, and many are tied to each other. Global warming tops off the chaotic mix.

Nevertheless, scientists in the United States have produced some of the most sophisticated tools to monitor and predict drought. Resource planners and policymakers rely mainly on the U.S. Drought Monitor, an online map of dryness that has been updated weekly since it was unveiled in 2000 by the Department of

## update

**DRYING UP:** A screen shot from the U.S. Drought Monitor in late July. Other countries are working on similar systems.

IMAGE: NATIONAL DROUGHT MITIGATION CENTER

Agriculture, the National Oceanic and Atmospheric Administration (NOAA), and the NDMC. The monitor combines several mathematical indices calculated by feeding computer models with temperature, precipitation, and soil moisture data. The physical data comes from NOAA's polar-orbiting satellites and on-the-ground temperature, rain, and snow gauges. "The U.S. leads in drought monitoring," Fuchs says. "Many other countries are trying to emulate the U.S. Drought Monitor."

While monitoring has been done for decades, forecasting drought is still in its infancy. Today, it blends science and art, and the only place it's done on a national scale is at NOAA's Climate Prediction Center (CPC) in Camp Springs, Md. Twice every month, meteorologists there subjectively produce the U.S. Seasonal Drought Outlook, which predicts conditions

for the next three months.

To create the Drought Outlook, scientists mix data from the Drought Monitor with soil moisture information and the CPC's three-month forecast of temperature and rainfall. They also incorporate current climate conditions along with past heat and precipitation.

The temperature and rainfall outlook comes from NOAA's climate model, which runs on an IBM Power6 mainframe computer, and takes half a day to finish one simulation run. The model, which was unveiled seven years ago, couples ocean and atmosphere models that had to be run separately before, explains Dan Collins, a forecaster at the CPC. The newer, improved version that went into operation this year also includes things like sea- and land-ice melting and changing levels of carbon dioxide in the atmosphere.

## 5 HOURS 49 MINUTES

Time from Kazakhstan to the International Space Station using a new launch plan tested in August. Ordinarily the trip takes three days.

Collins says that more-powerful computers would make it possible to include more-detailed physics and more climate system components. "You want to better simulate the way in which clouds are formed or water evaporates from soil," he says. Greater computing prowess would also mean that each simulation step would cover a shorter time and distance—a few minutes and a few kilometers as opposed to the hours and tens of kilometers used now. This would improve the ability to capture smaller, more rapid

changes in temperature and precipitation.

Other advances expected in the coming years include more extensive ground observation networks and NOAA's next-generation polar satellite, which is scheduled for launch in 2016 and will be equipped with advanced visual and infrared imagers that produce data with a higher temporal and spatial resolution. These will give better temperature, precipitation, and soil moisture data, which will

improve the accuracy of drought prediction, says Fuchs. Already, the Drought Monitor maps have gotten more refined over 12 years because of resolution improvements in satellite gear, he says. What's more, NASA is developing satellite-based instruments that are better at measuring soil moisture, he adds. The Drought Monitor currently uses soil moisture that is indirectly estimated by computer models based on rainfall and temperature observations.

Collins anticipates that longer-term drought prediction could be possible five years from now. That's when NOAA scientists are expecting to next upgrade the climate model, to include decade-long climate fluctuations. They hope to do this by simulating known long-term ocean fluctuations such as the Atlantic multidecadal oscillation. Fuchs says, "I anticipate continuing to see drought monitoring and prediction evolve, and technology will be a driving factor."

## the big picture

### The Final Frontier

The space shuttle *Enterprise* has completed its last trek. The winged craft, shown at the Intrepid Sea, Air & Space Museum, in New York City, has been on public display there since 19 July. It began its life in 1976 as the original prototype of the fleet that would famously take off like rockets and land like planes. Though the shuttle was named after the fictional *USS Enterprise* from the TV show "Star Trek," it has never flown in space. The craft, built without an engine or heat shields, was first used to test the design's gliding and landing ability before the introduction of its successor shuttles. In retirement, it became a source for parts used in newer shuttles and in the post-accident investigation of the 2003 shuttle *Columbia* disaster.

# careers

## WHERE THE JOBS ARE: 2012

In a warming job market, the hottest sector is power

NEW ELECTRICAL and computer engineers stepping out into the real world this year might not get the multiple job offers and off-the-charts starting pay of the precrash days, but they can rest assured that their skills will be put to good use. Hiring is up by 10 percent over last year, and pay has increased slightly for electrical and computer engineers of the class of 2012.

EEs looking for stable jobs and high salaries should consider the power

sector in particular. In the United States, millions of government and industry dollars are now flowing into a reviving utility industry. Renewables and the smart grid are about to breathe new life into a rusty power transmission and distribution system, while half of the workforce is expected to retire in the next 5 to 10 years, creating thousands of jobs. The U.S. utility industry hired 120 000 new bachelor's graduates this year across majors, and it paid the highest starting salaries—averaging US \$64 000—among all industries, according to the National Association of Colleges and Employers (NACE)

in Bethlehem, Pa. Gregory Reed, director of the Power & Energy Initiative at the University of Pittsburgh, says that EE masters graduates with a power engineering concentration are starting at around \$80 000, while recent Ph.D.s are making over \$90 000.

Meanwhile, in China and India, the power grid is nascent, and all energy sectors, from coal and nuclear to solar and wind, are undergoing prolific growth. “They need engineers more than ever,” Reed says.

“I don’t think there’s anything more exciting than this career right now,” says Wanda Reder, a vice president at S&C Electric Co., in Chicago. “There are a lot of empty seats due to attrition. At the same time, there’s a lot of new technology coming in. We need really good minds to figure out how to integrate those technologies and operate the power system better, more efficiently, and cleaner than has been possible in the past.”

The energy jobs outlook in Europe is more mixed. Utilities there face the same aging workforce issues as in the United States: Between 19 and 38 percent of workers at eight major European electricity companies are due to retire within the next decade. However, not all those positions will need to be filled, and many of them will require different skills, says Charlotte Renaud, a policy officer at the electricity industry association Eurelectric,

in Belgium. That’s mainly because of a phaseout of nuclear power in many EU countries and an increasing switch to renewables. “You need less people to run windmills than a nuclear power plant,” she says.

Outside the power industry, salary offers to engineering grads haven’t changed much in a year overall, according to NACE. Among engineers, computer and aerospace engineers are the top earners, bringing in median offers of \$67 800 and \$64 200. And as was the case a year ago, electrical engineers saw the biggest jump in starting salaries—2.2 percent over last year—to reach \$57 300.

The profusion of smartphones and tablets, the health-care industry’s increasing use of computer systems, and concerns about cybersecurity are all keeping software engineers in high demand, according to the U.S. Bureau of Labor Statistics. The median salary of new computer-science grads went up by 2.4 percent to \$56 383, with new graduates being hired in the information sector making an impressive \$64 400, according to NACE. According to the Bureau of Labor Statistics, employment for software developers should grow by 30 percent in the decade leading up to 2020: The average growth rate for all occupations is 14 percent.

# education

## Review: MITx's Online Circuit and Analysis Course

The university's first massively scaled course is not for casual students

MIT'S ANANT AGARWAL has a thing for chain saws. The professor of electrical engineering and computer science said so himself as he welcomed his vast horde of online students. And it *was* a horde: More than 150 000 of us from dozens of countries had signed up for MIT's inaugural MOOC, or massively open online course, which began in early March and ended in June. The course, dubbed 6.002x, was an adaptation of MIT's undergraduate class in circuit design and analysis and was part of the university's MITx initiative, which aims to offer anyone with an Internet connection access to a selection of its courses. Participants were lured by some powerful enticements: MIT's prestige, the opportunity to

learn from a renowned professor, and the price—free. Although MIT has made course materials publicly available for over a decade, this is its first online class involving scheduled instruction, supervision, and testing. Only participants who formally signed up for the 6.002x course were eligible to earn a credential certifying successful completion; MIT has not announced when the course will be offered again.

In an early recorded lecture, which plays as a YouTube video, Agarwal dons full Blues Brothers regalia to demonstrate noise margins, a chain saw his source of system noise as he bobs to a disco tune, while laughter resounds in the classroom. But any 6.002xers who mistook his professorial charisma for a lack

of seriousness, expecting a gentle tiptoe through circuitry basics, were swiftly disillusioned. The curriculum, identical to that of the classroom MIT course, was challenging. Spanning almost the entirety of the 1000-page course textbook, which Agarwal coauthored, each of the 14 weeks of class included 2 to 4 hours of lectures, online exercises interspersed with lecture sequences, a homework problem set, and an online lab, which involved building and testing simulated circuits. Optional video tutorials supplemented the lectures with solved problems and math refreshers. Midterm and final examinations rounded out the busy calendar.

"Massively open" means massively scalable, and the MITx organizers managed to create an impressive suite of shared resources. These included an online version of the course textbook; an always-available "circuit sandbox" lab environment complete with virtual signal probes, sweep generators, and oscilloscopes; and—most critically—a lively and well-managed discussion board.

So how did it all compare to a live class? Astonishingly well, it seemed to me. The ability to pause lectures, which were delivered on virtual blackboard slides that Professor Agarwal marked up as he spoke, was something of a revelation: Gone was the multitasking stress of trying to take notes and listen at the same time. The lecture sequences "remembered" where you left off, so segments could be viewed outside a fixed schedule. And the lectures themselves felt surprisingly personal.

The problem sets, while self-marking, tended to escalate in difficulty. You entered an answer, clicked on the "check" button, and after a pregnant pause, the grading software delivered a scarlet letter X or a green check mark. For the exercises and homework problems, you could answer as many times as

# tools & toys

you liked. Participants quickly learned one reason that engineering is so amenable to online instruction: Guessing is pointless, and answers are not a matter of opinion. Hours were spent fighting the scarlet letter, and when the green check mark of achievement at last arrived, it did so with embarrassingly potent psychic force. But the “aha moment,” as Agarwal likes to call it, must necessarily precede it.

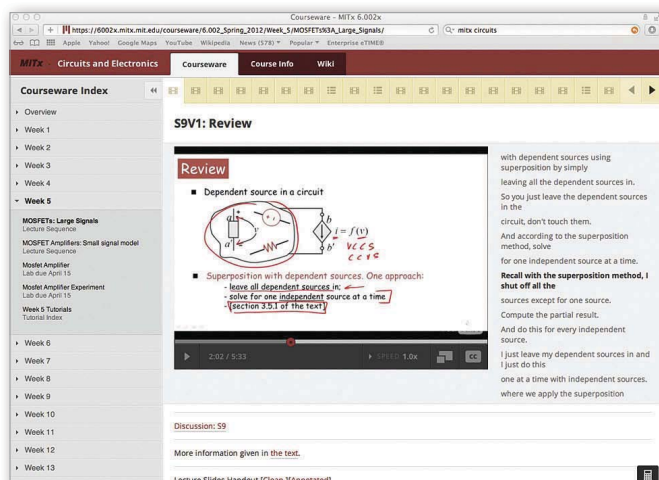

Here is where the discussion board proved indispensable. While many a pleasant undergraduate hour may be spent groping for enlightenment with equally clueless classmates, posting a question in this forum

could get you the right answer in 20 minutes—or provoke some fascinating exchanges. The social dimension of the educational experience did not feel slighted by the remote format.

Of the original city-size class population, 5800 passed the final exam, and 7157 earned enough credit overall to pass the course and receive a certificate of completion. MITx offers no course credit, and who knows what value the marketplace will ascribe to the credential we received? But we’ve dipped our oars in MIT waters, and we’re secretly, insufferably, pleased with ourselves.

—STEVEN J. FRANK

*A version of this article appeared online in July 2012.*

**CLASS SYSTEM:** MITx course lectures are delivered using a virtual blackboard. Students listen to a prerecorded narration, watch slides being marked up, and read a line-by-line transcript as the lecture proceeds. Supplementary material, such as video demonstrations, can also be called up on demand.

## REFORMULATING DISPLAYS

New recipes for making screens will power the next generation of televisions

THE MESSAGE from Display Week, June’s annual gathering of the Society for Information Display, is that while the current big trend in the industry—smart televisions—is driven by processors and software [see “Smart TV,” *IEEE Spectrum*, July 2012], the momentum for the next wave of display products is coming from advances in materials. These advances will mean bigger screens and higher resolutions at lower cost and could even open the door to radically new devices, such as an information display that wraps around a cylindrical pillar.

The materials in question are used in a critical component of flat-panel displays: the backplane responsible for turning pixels on and off. If you tear down a typical LCD, you’ll find that the actual pixel

switching is done by thin-film transistors. Generally, these TFTs are formed on a thin layer of silicon deposited on a glass substrate, and these layers make up the backplane. The simplest and cheapest way to deposit the silicon layer produces amorphous silicon. However, the electrical properties of amorphous silicon translate to relatively large transistors and thus relatively large pixels—adequate for the LCD panels of yesteryear, but at the resolution of Apple’s Retina screens, for example, smaller transistors are needed.

One way to produce tiny transistors is to make the backplane using a single crystal of silicon, similar to the wafers that microprocessors are made from. However, it’s not feasible to make wafers large enough for displays. The

**SCREEN SHOTS:** Sharp used the new IGZO (indium gallium zinc oxide) material to create a prototype of a flexible 3.4-inch OLED display [opposite page]. Cheaper manufacturing processes and displays that can be built to fit curved surfaces are likely to result from backplanes made with very thin glass, such as Corning's Willow Glass [this page]. PHOTO: CORNING

current compromise solution is to use a laser annealing process that heats and cools a regular amorphous silicon layer. The result is a layer containing many small crystals, like frost on a car window. Much smaller transistors can be fabricated on this polycrystalline silicon, or polysilicon, than with amorphous silicon. The problem is that laser annealing works fine for the small- to medium-size displays used with cellphones and tablets, but not as well at the scale of TVs.

Fortunately, at Display Week 2012, in Boston, an entirely different approach was bearing fruit after about 30 years of research and development. Instead of silicon in the backplane, engineers are turning to a metal oxide composed of

indium, gallium, and zinc in equal parts, giving the material its name: IGZO, for indium gallium zinc oxide. Its electrical properties are roughly between those of amorphous silicon and polysilicon, and IGZO is compatible with existing LCD manufacturing technology.

Sharp showed a 6.1-inch LCD, suitable for mobile devices, with an IGZO backplane and an incredible 498-pixel-per-inch resolution (for comparison, a Retina display on an iPhone has 326 ppi). In addition to providing higher resolutions without an expensive polysilicon backplane, the metal oxide is more energy efficient than amorphous silicon.

Going beyond LCDs, IGZO has made it possible to create large backplanes that can provide the power required to

drive organic light-emitting diode displays. OLEDs are challenging the dominance of LCDs, because each OLED pixel emits its own light, just as the pixels of old cathode ray tube TVs did (LCDs work by selectively filtering a backlight). Emitting rather than filtering light eliminates the narrow viewing angle problem of LCDs. OLEDs can also be more power efficient than LCDs, dispensing with the need for a continuously illuminated backlight, and can produce deeper blacks for better picture contrast.

OLEDs are already popular in small, high-end mobile device displays. The new metal oxide backplanes make it possible to create much larger panels, and LG has demonstrated 55-inch 1080p (1920- by 1080-pixel) OLED TVs that it intends to start selling by the end of this year. (Samsung also intends to ship a 55-inch OLED HDTV in 2012, although the company's backplane reportedly uses polysilicon rather than IGZO.)

IGZO also allows for smaller OLED pixels than are possible with amorphous silicon backplanes. Sharp has produced a prototype 13.5-inch panel in partnership with Semiconductor Energy Laboratory Co. with an amazing 3840- by 2160-pixel resolution. This is the equivalent of four 1080p panels tiled together. The

panel has 326 ppi, extremely fine for a screen this large (for comparison, the latest iPad display comes in at 264 ppi).

However, even bigger changes in displays could come from the material used as the foundation of backplanes: glass.

Last year, both Corning and Asahi Glass Co. demonstrated glass substrates that were just 0.1 millimeters thick. This year, Corning announced the commercial availability of its new glass under the brand name Willow. Asahi has also put its new glass on the market, including a version laminated to a thicker carrier sheet so that it can be used in existing LCD manufacturing lines.

These glasses are thin enough to roll up into spools, which makes it possible to use them in roll-to-roll production. Until now, LCDs and OLEDs have been fabricated on discrete rectangular sheets of glass that are processed in batches. Roll-to-roll production, even for just a handful of manufacturing steps, could be much faster and more efficient, driving production costs down. In addition to making finished products that cost—and weigh—much less, roll-to-roll production using thin glass could lead to novel applications such as very large displays, or screens that conform to curves in walls or other architectural features.

## I, PUBLISHER

Electronic books offer authors a direct channel to readers

JOURNALIST A.J. Liebling once famously noted, “Freedom of the press is guaranteed only to those who own one.” But with the advent of electronic publishing—and ancillary technologies such as online stores, e-readers, and print-on-demand (POD) systems—anyone with a computer and an Internet connection can be a publisher. For better or worse, whether they’re barely literate neophytes or *New York Times* best-selling authors, writers can publish whatever they want without having to get

approval from an agent, a selection committee, or a peer review process. Online retailers like [Amazon.com](http://Amazon.com), Apple, and Barnes & Noble also pay a significantly higher percentage of per-copy revenue than traditional publishing houses, giving writers the potential to earn much more money. So it’s no wonder that many authors (including us) are bypassing conventional publishers.

True, e-publishing means that authors are responsible for all stages of a book’s production, including graphic design and marketing, but this isn’t that much different from the trend authors have experienced with many print book publishers in recent years.

For example, for our last three books, our publishers (Peachpit Press and John Wiley & Sons) provided a template for our word processing program to allow us to format our manuscripts so they could be sent directly to a printing house. We were expected to do (or pay someone else to do) our own editing, copyediting, and proofreading, as well as secure permissions to quote copyrighted material. The publishers’ prepublication publicity consisted solely of sending out press releases and review copies.

While publishing electronically doesn’t help with getting a book edited or marketed, it does offer writers direct access to

many millions of potential readers. So how is it done?

A narrative book is the easiest type to e-publish. Essentially, you write it as you normally would, with a word processor. The preferred software is Microsoft Word, because it’s accepted by all e-book services. Until recently, we recommended against Corel’s WordPerfect, because it tended to generate code that didn’t play well with some e-book formats. However, the recently released WordPerfect Office X6 has an e-book template especially designed for the Mobipocket (MOBI) format used by the Amazon Kindle. Corel says it will soon be supporting the EPUB format as well, which is used by just about every other e-reader, including Apple’s iPad and iPhone, Barnes & Noble’s Nook, and the Sony Reader.

You’ll need to change some of your word processing habits. That’s because e-readers have their own way of placing and flowing text, depending on things like the reader’s preferences about font size. To get the best and most consistent results, for instance, don’t use tabs or spaces to define where text will be positioned (such as at the beginning of a paragraph). Instead, use the word processor’s Styles feature to define the arrangement and properties of different

pieces of text, such as chapter headings, quotes, bullet points, and paragraphs. If you've done this styling correctly, converting a document into a ready-for-sale e-book can be simply a matter of uploading the file to an e-publisher's website. Just about everything you'll need to know about using a word processor for e-publishing is included in the *Smashwords Style Guide*, which is available free (more about Smashwords below).

If a book contains a lot of graphics or interactive elements, however, a word processor won't be enough. You'll need a desktop publishing (DTP) program. The top professional DTP programs—Adobe InDesign and Quark Xpress—both support e-book publishing. They can be used to insert photos, tables, illustrations, video, or interactive elements into a book. However, a big proviso is that different e-book formats have varying levels of support for visual and interactive elements. The more complex an e-book is, the fewer e-readers will be able to display it properly. Converting a manuscript to an e-book format is done either directly by the DTP program or when the file is uploaded to an online bookstore.

An author's first upload should be to Amazon. Amazon is far and away

the largest bookstore in the world; it's been estimated that Amazon's sales represent up to 60 percent of all e-book sales (and about 75 percent of online printed book sales). In the United States, Amazon's royalties to authors are 35 to 70 percent, depending on factors such as the book's file size and where it will be sold. Authors create an account at Kindle Direct Publishing and follow the prompts to upload a book. The KDP site is very helpful, but valuable insights are also available on the Writers Café of the Kindleboards.

You can upload manuscripts to KDP in several formats: Word, EPUB, .txt, zipped HTML, Adobe PDF, or of course, MOBI. KDP will convert the format as required and check it to make sure the manuscript conforms to Amazon's standards for how the text should be arranged. You can preview onscreen how your book will look on the company's various Kindle devices. If you don't like what you see, you can reedit the manuscript and upload a new file.

Amazon would like writers to publish on its site only and nowhere else. So it offers programs for authors who give the company exclusivity, such as participation in Amazon's "borrowing library," in which the author gets paid every time an e-book is

lent to an Amazon Prime member. That exclusivity is for a period of 90 days, renewed automatically unless you notify the company otherwise.

The second site that we recommend is Smashwords, a one-stop shop for e-publishing (and the same folks who offer that free guidebook on e-publishing). A single upload of a Word manuscript will generate e-book files in multiple formats—in addition to EPUB and MOBI, it will also create files in the PDF and HTML formats, among others. Like Amazon, Smashwords will check a document to make sure it meets the company's formatting

including Apple's iBooks store, Barnes & Noble, Kobo, and others. (Yes, you could submit your work individually to each of those sites—and not have to give Smashwords a cut of your sales in addition to whatever the stores take—but we have found the service a nice time-saver.) In addition, once Smashwords has converted your manuscript, you can download and use the e-book files for your own purposes (including selling your book on your own website and keeping all the revenue for yourself). The royalty for books sold on Smashwords is 85 percent minus a transaction fee (which brings it down to

## Paper Lives!

WRITERS WHO WANT to offer traditional paper books can also benefit from the revolution in publishing technology. A number of print-on-demand services allow you to list digitally produced books; when a reader buys one, a copy is printed, bound, and shipped. The process is, however, a little more complex than creating purely electronic books. A short guide to what's involved and a listing of some print-on-demand services are available at <http://www.spectrum.ieee.org/pod0912>.

standards (which are a bit stricter than Amazon's). If Smashwords determines that the formatting meets a certain quality level, then your e-book will qualify for its Premium treatment. This means that Smashwords, in addition to selling your book on its own site, will submit it to a bunch of online stores,

about 82 percent). Royalties from Smashwords sales on other sites is 60 percent.

And that's it! Now it's up to you to spread the word and get people clicking and downloading.

## reflections

BY ROBERT W. LUCKY

## Disposable Electronics

IN THE BACK of my closet is a padded leather case containing my precious 35-mm film camera and lenses. I thought the investment in these things would last me forever. Now, however, that leather case is cracking, and the camera goes unused. Meanwhile, in a desk drawer lies a careless jumble of digital cameras, including the most recently purchased one. I feel no special affinity for them—they just come and go, and rather quickly at that.

Cellphones are just as bad. I understand that about a half million are thrown away every day in the United States alone. This means that the average life span is about two years, which puts dog years to shame. In human terms, the cellphone loses about a month of its life every day.

This all suggests a new perspective—for both users

and designers—about electronics as disposable systems. As a consumer, I've had a hard time getting it right.

When a new gadget is announced, I feel an irresistible pull. It's an emotional thing, because I know that this will be version 1.0, full of bugs and ripe for improvement. No sooner do I buy this first model than a second-generation model hits the market. Then I face a choice: Stick with the old clunky one or put the same investment into the new one? Millions of people have experienced this dilemma, with the iPad, already in its third generation, as a leading example. When do you buy a new one? I remember worrying about how much memory I should get and whether I should purchase a protective film for the screen. But then I

thought: Why bother? I won't have this thing very long.

How does this new calculus of consumption affect design? The approach would seem to be the polar opposite of that taken for military equipment, which focuses on durability, robustness, and longevity. The design cycle there takes years and ends with relatively small production quantities and high prices. Meanwhile, the commercial equivalents will have gone through multiple generations of large production runs and ever-lower prices.

I suspect that engineers don't really worry much about the philosophy and just try to do the best job they can. The question of timing must be foremost. You can't miss a generation in the market or your supernova company will turn into a dwarf star. We've seen it happen. So there's

no time to tweak the design, and at some early point you have to stop seeking improvements or looking for bugs and just go with what you have. That's difficult for an engineer. Perhaps there is some analogy to the fruit market, where they ship green bananas and suggest a sell-by date. The big difference is that the electronics don't ripen on the way to the store. Quite the opposite.

What about the supposition that nobody is going to upgrade this thing? Maybe it's okay to glue the battery in, and perhaps a USB port would be an unnecessary expense. But there is a fine line past which it starts to look like the designer is going out of his way to ensure that we buy the next version instead of upgrading. When the memory is soldered in and special tools are required to remove the back, we can be forgiven our suspicions.

The chaos of time pressure comes in the context of dealing with a tremendously complex system. I think only an engineer has any appreciation of the deep complexity of a cellphone, largely hidden in the fossilized chips that have evolved over the fast-moving generations. I can never quite get over the experience of opening the back of a cellphone and seeing that there is apparently nothing inside—just a big battery and display. I think of it as a true work of art, but its transience may make a consumer think of it in terms of what it will soon be—a piece of junk.

I got my present cellphone about a year ago. It's already showing signs of senility, almost ready to join the digital-camera graveyard in the desk drawer. □

DANIEL HERTZBERG

## Discover the Latest Titles from Wiley-IEEE Press!

### Frequency Stability Introduction and Applications

Venceslav F. Kroupa

**9781118159125, Hardcover, 328pp, \$99.95, August 2012, Wiley-IEEE Press**

This introductory text of frequency stability offers discussion of the noise from the practical and theoretical points of view, proceeding with investigation of frequency and time fluctuations in resonators, and continue with stability of both of standard and practical microwave oscillators.

### An Introduction to Audio Content Analysis Applications in Signal Processing and Music Informatics

Alexander Lerch

**9781118266823, Hardcover, 272pp, \$125, July 2012, Wiley-IEEE Press**

Written by a well-known expert in the field, this book provides quick access to different analysis algorithms and allows comparison between different approaches to the same task, making it useful for newcomers to audio signal processing and industry experts alike.

### Nanometer Frequency Synthesis Beyond the Phase-Locked Loop

Liming Xiu

**9781118162637, Hardcover, 344pp, \$125, July 2012, Wiley-IEEE Press**

This text presents a latest technology in frequency synthesis. The technology includes three key components: Time-Average-Frequency, Flying-Adder architecture, and Digital-to-Frequency converter. The coverage presents the case, through real application examples, that this Flying-Adder technology creates a new frontier for modern IC design.

### Organic, Inorganic and Hybrid Solar Cells Principles and Practice

Ching-Fuh Lin, Wei-Fang Su, Chih-I Wu, I-Chun Cheng

**9781118168530, Hardcover, 288pp, \$99.95, August 2012, Wiley-IEEE Press**

Focusing on all aspects of realizing low-cost and long life solar cells, the text covers inorganic, organic, and hybrid materials. This unique guide provides an unparalleled description of the functioning principles and fabrication techniques of organic-inorganic composite solar cells.

### Practical Database Programming with Visual Basic.NET, 2nd Edition

Ying Bai

**9781118162057, Paperback, 896pp, \$99.95, June 2012, Wiley-IEEE Press**

Unlike most database programming books, which overwhelm readers with large amount of code, this book employs a new, more reader-friendly approach. Now in a new edition updated with the latest tools and information, it lays out to readers, in particular college students, how to develop professional and practical database programs in Visual Basic.NET environment by using Visual Studio.NET Data Tools and Wizards related to ADO.NET 4.0.

### Reinforcement and Systemic Machine Learning for Decision Making

Parag Kulkarni

**9780470919996, Hardcover, 312pp, \$115, July 2012, Wiley-IEEE Press**

*Reinforcement and Systemic Machine Learning for Decision Making* explores a newer and growing avenue of machine learning algorithm in the area of computational intelligence. This book focuses on reinforcement and systemic learning to build a new learning paradigm, which makes effective use of these learning methodologies to increase machine intelligence and help us in building the advance machine learning applications.

### Reliability and Availability of Cloud Computing

Eric Bauer, Randee Adams

**9781118177013, Hardcover, 352pp, \$79.95, August 2012, Wiley-IEEE Press**

This book addresses IS/IT architects, developers, program managers, product managers, and quality managers who are considering or responsible for applications that will be virtualized or deployed on a cloud. Topics covered include reliability risks, meeting customer's expectations, and how to maximize service availability and reliability of virtualized and cloud-based deployments.

### Remote Sensing and Actuation Using Unmanned Vehicles

Haiyang Chao, YangQuan Chen

**9781118122761, Hardcover, 232pp, \$99.95, August 2012, Wiley-IEEE Press**

This book fills the gap in the field between research and real-world applications, providing scientists and engineers with essential information on how to design and employ networked unmanned vehicles for remote sensing and distributed control purposes. Target scenarios include environmental or agricultural applications such as river/reservoir surveillance, wind profiling measurement, and monitoring/control of chemical leaks.

### Satellite Communications Payload and System

Teresa M. Braun

**9780470540848, Hardcover, 400pp, \$95, August 2012, Wiley-IEEE Press**

This book provides a unique combination of practical payload systems engineering and communications theory and applications. It features new analytical material by the author to save satellite power and details on dealing with interference from other communication systems and atmospherics.

### Streamlining Digital Signal Processing A Tricks of the Trade Guidebook, 2nd Edition

Richard G. Lyons

**9781118278383, Paperback, 496pp, \$ 79.95, June 2012, Wiley-IEEE Press**

This book presents recent advances in DSP to simplify, or increase the computational speed of, common signal processing operations. The topics describe clever DSP tricks of the trade not covered in conventional DSP textbooks. This material is practical, real-world, DSP tips and tricks as opposed to the traditional highly-specialized, math-intensive, research subjects directed at industry researchers and university professors.

# *The Truth About* Terahertz

ANYONE HOPING TO EXPLOIT  
THIS PROMISING REGION  
OF THE ELECTROMAGNETIC  
SPECTRUM MUST CONFRONT  
ITS VERY DAUNTING PHYSICS

BY CARTER M. ARMSTRONG

*Illustration By Chad Hagen*

WITHOUT ENDLESSLY TRANSFER HUGE FILES in the blink of an eye! Detect bombs, poison gas clouds, and concealed weapons from afar! Peer through walls with T-ray vision! You can do it all with terahertz technology—or so you might believe after perusing popular accounts of the subject.

The truth is a bit more nuanced. The terahertz regime is that promising yet vexing slice of the electromagnetic spectrum that lies between the microwave and the optical, corresponding to frequencies of about 300 billion hertz to 10 trillion hertz (or if you prefer, wavelengths of 1 millimeter down to 30 micrometers). This radiation does have some uniquely attractive qualities: For example, it can yield extremely high-resolution images and move vast amounts of data quickly. And yet it is nonionizing,

meaning its photons are not energetic enough to knock electrons off atoms and molecules in human tissue, which could trigger harmful chemical reactions. The waves also stimulate molecular and electronic motions in many materials—reflecting off some, propagating through others, and being absorbed by the rest. These features have been exploited in laboratory demonstrations to identify explosives, reveal hidden weapons, check for defects in tiles on the space shuttle, and screen for skin cancer and tooth decay.

But the goal of turning such laboratory phenomena into real-world applications has proved elusive. Legions of researchers have struggled with that challenge for decades.

The past 10 years have seen the most intense work to tame and harness the power of the terahertz regime. I first became aware of the extent of these efforts in 2007, when I cochaired a U.S. government panel that reviewed compact terahertz sources. The review's chief goal was to determine the state of the technology. We heard from about 30 R&D teams, and by the end we had a good idea of where things stood. What the review failed to do, though, was give a clear picture of the many challenges of exploiting the terahertz regime. What I really wanted were answers to questions like, What exactly are terahertz frequencies best suited for? And how demanding are they to produce, control, apply, and otherwise manipulate?

So I launched my own investigation. I studied the key issues in developing three of the applications that have been widely discussed in defense, security, and law-enforcement circles: communication and radar, identification of harmful substances from a distance, and through-wall imaging. I also looked at the 20 or so compact terahertz sources covered in the 2007 review, to see if they shared any performance challenges, despite their different designs and features. I recently updated my findings, although much of what I concluded then still holds true now.

My efforts aren't meant to discourage the pursuit of this potentially valuable technology—far from it. But there are some unavoidable truths that anyone working with this technology inevitably has to confront. Here's what I found.

**ALTHOUGH TERAHERTZ** technology has been much in the news lately, the phenomenon isn't really new. It just

went by different names in the past—near millimeter, submillimeter, extreme far infrared. Since at least the 1950s, researchers have sought to tap its appealing characteristics. Use of this spectral band by early molecular spectroscopists, for example, laid the foundation for its application to ground-based radio telescopes, such as the Atacama Large Millimeter/submillimeter Array, in Chile. Over the years a few other niche uses have emerged, most notably space-based remote sensing. In the 1970s, space scientists began using far-infrared and submillimeter-wave spectrometers for investigating the chemical compositions of the interstellar medium and planetary atmospheres. One of my favorite statistics, which comes from astronomer David Leisawitz at NASA Goddard Space Flight Center, is that 98 percent of the photons released since the big bang reside in the submillimeter and far-infrared bands, a fact that observatories like the Herschel Space Observatory are designed to take advantage of. Indeed, it's safe to say that the current state of terahertz technology rests in good measure on advances in radio astronomy and space science.

But orbiting terahertz instruments have a big advantage over their terrestrial counterparts: They're in space! Specifically, they operate in a near-vacuum and don't have to contend with a dense atmosphere, which absorbs, refracts, and scatters terahertz signals. Nor do they have to operate in inclement weather. There is no simple way to get around the basic physics of the situation. You can operate at higher altitudes, where it's less dense and there's

less moisture, but many of the envisioned terahertz applications are for use on the ground. You can boost the signal's strength in hopes that enough radiation will get through at the receiving end, but at some point, that's just not practical, as we'll see.

Obviously, atmospheric attenuation poses a problem for using terahertz frequencies for long-range communication and radar. But how big a problem? To answer that question, I compared different scenarios for horizontal transmission at sea level—good weather, bad weather, a range of distances (from 1 meter up to 6 kilometers), and specific frequencies between 35 gigahertz and 3 terahertz—to determine how much the signal strength degrades as conditions vary. For short-range operation—that is, for signals traveling 10 meters or less—the effects of the atmosphere and bad weather don't really come into play.

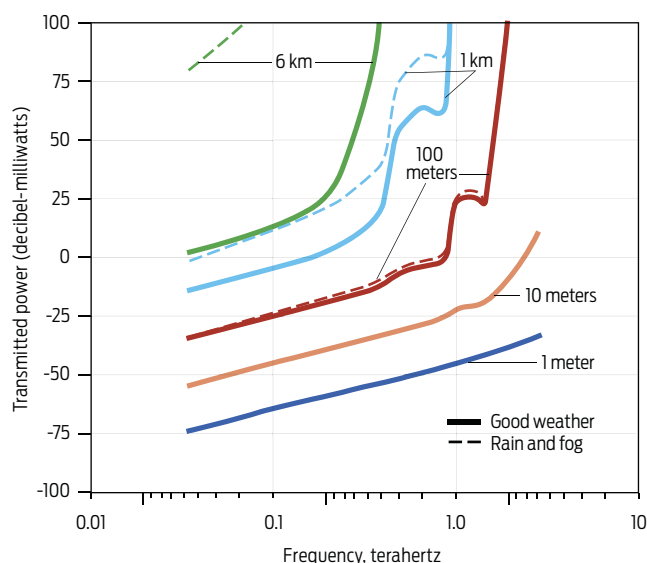

Try to send anything farther than that and you hit what I call the “terahertz wall”: No matter how much you boost the signal, essentially nothing gets through. A 1-watt signal with a frequency of 1 THz, for instance, will dwindle to nothing after traveling just 1 km. Well, not quite nothing: It retains about  $10^{-30}$  percent of its original strength. So even if you were to increase the signal's power to the ridiculously high level of, say, a petawatt, and then somehow manage to propagate it without ionizing the atmosphere in the process, it would be reduced to mere femtowatts by the time it reached its destination. Needless to say, there are no terahertz sources capable of producing anything approaching

#### ATMOSPHERIC EFFECTS:

Terrestrial signals sent at terahertz frequencies can experience extreme atmospheric absorption, due primarily to water vapor and oxygen. For horizontal transmission at sea level and normal humidity, as shown here, the signal attenuation clearly peaks between 1 and 10 terahertz.

ILLUSTRATIONS: GEORGE RETSECK

**TERAHERTZ WALL:** The power needed to send data at terahertz frequencies would be impractically high in many cases. For a line-of-sight terrestrial communication link using fixed-gain antennas, shown here, transmitting at distances of less than 100 meters is the only way to avoid the “terahertz wall.”

good conductive material, you won't get any image at all. If the wall contains any of the common insulating or construction materials, you might still get serious attenuation, depending on the material and its thickness as well as the frequency you are using. For example, a 1-THz signal passing through a quarter-inch-thick piece of plywood would have 0.0015 percent of the power of a 94-GHz signal making the same journey. And if the material is damp, the loss is even higher. (Such factors affect not just imaging through barriers but also terahertz wireless networks, which would require at the least a direct line of sight between the source and the receiver.) So your childhood dream of owning a pair of “X-ray specs” probably isn't going to happen any time soon.

It's true that some researchers have successfully demonstrated through-wall imaging. In these demonstrations, the radiation sources emitted impulses of radiation across a wide range of frequencies, including terahertz. Given what we know about attenuation at the higher frequencies, though, some scientists who've studied the results believe it's highly likely that the imaging occurred not in the terahertz region but rather at the lower frequencies. And if that's the case, then why not just use millimeter-wave imagers to begin with?

Before leaving the subject of imaging, let me add one last thought on terahertz for medical imaging. Some of the more creative potential uses I've heard include brain imaging, tumor detection, and full-body scanning that would yield much more detailed pictures than any existing technology and yet be completely safe. But the reality once again falls short of the dream. Frank De Lucia, a physicist at Ohio State University, in Columbus, has pointed out that a terahertz signal will decrease in power to 0.0000002 percent of its original strength after traveling just 1 mm in saline solution, which is a good approximation for body tissue. For now at least, terahertz medical devices will be useful only for surface imaging of things like skin cancer and tooth decay and laboratory tests on thin tissue samples.

**SO THOSE ARE SOME** of the basic challenges of exploiting the terahertz regime. The physics is indeed daunting, but that hasn't prevented developers from continuing to pursue lots of different terahertz devices for those and other

a petawatt; the closest is a free-electron laser, which has an output in the low tens of megawatts and isn't exactly a field-deployable device. (For comparison, the output power of today's compact sources spans the 1-microwatt to 1-W range—more on that later.) And that's under ordinary atmospheric conditions. Rain and fog will deteriorate the signal even more. Attenuation that extreme all but rules out using the terahertz region for long-range ground-based communication and radar.

Another potentially invaluable and much hyped use for terahertz waves is identifying hazardous materials from afar. In their gaseous phase, many natural and man-made molecules, including ammonia, carbon monoxide, hydrogen sulfide, and methanol, absorb photons when stimulated at terahertz frequencies, and those absorption bands can serve as chemical fingerprints. Even so, outside the carefully calibrated conditions of the laboratory or the sparse environment of space, complications arise.

Let's say you're a hazmat worker and you've received a report about a possible sarin gas attack. Obviously, you'll want to keep your distance, so you pull out your trusty portable T-wave spectrometer, which works something like the tricorder in “Star Trek.” It sends a directed beam of terahertz radiation into the cloud; the gas absorbs the radiation with a characteristic spectral frequency signature. Unlike with communications or radar, which would probably use a narrowband signal, your spectrometer sends out a broadband signal, from about 300 GHz to 3 THz. Of course, to

ensure that the signal returns to your spectrometer, it will need to reflect off something beyond the gas cloud, like a building, a container, or even some trees. But as in the case above, the atmosphere diminishes the signal's strength as it travels to the cloud and then back to your detector. The atmosphere also washes out the spectral features of the cloud because of an effect known as pressure broadening. Even at a distance of just 10 meters, such effects would make it difficult, if not impossible, to get an accurate reading. Yet another wrinkle is that the chemical signatures of some materials—table sugar and some plastic explosives, for instance—are so remarkably nondescript as to make distinguishing one from another impossible.

By now, you won't be surprised to hear that through-wall imaging, another much-discussed application of terahertz radiation, also faces major hurdles. The idea is simple enough: Aim terahertz radiation at a wall of some sort, with an object on the other side. Terahertz waves can penetrate some—but not all—materials that are opaque in visible light. So depending on what the wall is made of and how thick it is, some waves will get through, reflect off the object, and then make their way back through the wall to the source, where they can reveal an image of the hidden object.

Realizing that simple idea is another matter. First, let's assume that the object itself doesn't scatter, absorb, or otherwise degrade the signal. Even so, the quality of the image you get will depend largely on what your wall is made of. If the wall is made of metal or some other

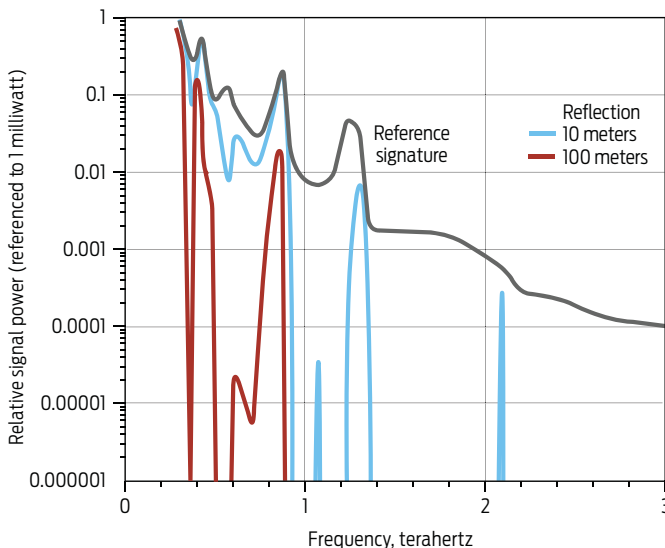

applications. So the next thing I looked at was the performance of systems capable of generating radiation at terahertz frequencies. I decided to focus on these sources—and not detectors, receivers, control devices, and so on—because while those other components are certainly critical, people in the field pretty much agree that what's held up progress is the lack of appropriate sources.

There's a very good reason for the shortage of compact terahertz sources: They're really hard to build! For many applications, the source has to be powerful enough to overcome extreme signal attenuation, efficient enough to avoid having to wheel around your own power generator, and small enough to be deployed in the field without having to be toted around on a flatbed truck. (For some applications, the source's spectral purity, tunability, or bandwidth is more important, so a lower power is acceptable.) The successful space-based instruments mentioned earlier merely detect terahertz radiation that celestial bodies and events naturally emit; although some of those instruments use a low-power source for improved sensitivity, they don't as yet attempt to transmit at terahertz frequencies.

The government review in 2007 loosely defined a compact terahertz source as having an average output power in the 1-mW to 1-W range, operating in the 300-GHz to 3-THz frequency band, and being more or less “portable.” (We chose average power rather than peak power because, ultimately, it's the average power that counts in nearly all of the envisioned applications.) In addition, we asked that the sources have a conversion efficiency of at least 1 percent—for every 100 W of input power, the source would produce a signal of 1 W or more. Even that modest goal, it turns out, is quite challenging.

The 2007 review included about 20 terahertz sources. I don't have room here to describe how each of these devices works, but in general they fall into three broad categories: vacuum (including backward-wave oscillators, klystrons, grating-vacuum devices, traveling-wave tubes, and gyrotrons), solid state (including harmonic frequency multipliers, transistors, and monolithic microwave integrated circuits), and laser and photonic (including quantum cascade lasers, optically pumped molecular lasers, and a vari-

#### THE UNDETECTED:

When attempting to identify unknown substances at a distance, nearly all of the terahertz signal will be lost or distorted by the atmosphere. Here, the gray line is a fictitious signature for a sample being probed in reflection mode. At distances of 10 meters and 100 meters [blue and red lines], the sample's distinct spectral features are washed away.

ety of optoelectronic RF generators). Vacuum devices and lasers exhibited the highest average power at the lower and upper frequencies, respectively. Solid-state devices came next, followed by photonic devices. To be fair, calling a gyrotron a compact source is quite a stretch, and while photonic sources can produce high peak power, ranging from hundreds of watts to kilowatts, they also require high optical-drive power.

Despite their considerable design differences and some variations in performance, these three classes of terahertz technology have similar challenges. One significant issue is their uniformly low conversion efficiency, which is typically much less than 1 percent. So to get a 1-W signal, you might need to start with kilowatts of input power, or greater. Other everyday electronic and optical devices are, by comparison, far more efficient. The RF power amplifier in a typical 2-GHz smartphone, for example, operates at around 50 percent efficiency. A commercial red diode laser can convert electrical power to light with an efficiency of more than 30 percent.

That low efficiency combined with the devices' small size leads to another problem: extremely high power densities (the amount of power the devices must handle per unit area) and current densities (the amount of current they must handle per unit area). For the vacuum and solid-state devices, the power densities were in the range of several megawatts per square centimeter. Suppose you want to use a conventional vacuum traveling-wave tube, or TWT, that's been

scaled up to operate at 1 THz. Such an apparatus would require you to focus an electron beam with a power density of multiple megawatts per square centimeter through an evacuated circuit having an inner diameter of 40  $\mu\text{m}$ —about half the diameter of a human hair. (The solar radiation at the surface of the sun, by contrast, has a power density of only about 6 kilowatts per square centimeter.) A terahertz transistor, with its nanometer features, operates at similarly high power density levels. And all of the electrical and photonic devices examined, even the quantum cascade laser, require high current densities, ranging from kiloamperes per square centimeter to multimega-amperes per square centimeter. Incidentally, the upper portion of that current density range is typical of what you'd see in the pulsed-power electrical generators used for nuclear effects testing, among other things.

Compact electrical and optical devices can handle conditions like that, but you're asking for trouble—if the device isn't adequately cooled, the internal power dissipation minimized, and the correct materials used, it can quickly melt or vaporize or otherwise break down. And of course, eventually you reach an upper limit, beyond which you simply can't push the power density and current density any higher.

As a device physicist, I was naturally interested in the relationship between the sources' output power and their frequency, what's known as power-frequency scaling. When you plot the device's average power along the  $y$ -axis and the frequency along the  $x$ , you want to see the flattest possible curve. Such

**POST YOUR  
COMMENTS**  
online at [http://  
spectrum.  
ieee.org/  
terahertz0912](http://spectrum.ieee.org/terahertz0912)

flatness means that as the frequency increases, the output power remains steady or at least does not plummet. In typical radio-frequency devices, such as transistors, solid-state diodes, and microwave vacuum tubes, the power tends to fall as the inverse of the frequency squared. In other words, if you double the frequency, the output power drops by a factor of four.

Most of the electrical terahertz sources we reviewed in 2007, however, had much steeper power-frequency curves that basically fell off into the abyss as they were pushed into the terahertz range. In general, the power scaled as the inverse of the frequency to the fourth, or worse, which meant that as the frequency doubled, the output power dropped by a factor of 16. So a device that could generate several watts at 100 GHz was capable of only a few hundred microwatts as it went to 1 THz. Lasers, too, fell off in power in the terahertz region faster than you would expect.

Given what I mentioned earlier about extreme signal attenuation in the terahertz region and the sources' low conversion efficiencies, this precipitous drop-off in power represents yet another high hurdle to commercializing the technology.

**FINE, YOU SAY**, but can't all of these problems be attributed to the fact that the sources are still technologically immature? Put another way, shouldn't we expect device performance to improve? Certainly, the technology is getting better. In the several years between my initial analysis and this article, here are some of the highlights in the device technologies I reviewed:

- The average power of micro-fabricated vacuum devices rose two orders of magnitude, from about 10  $\mu$ W to over a milliwatt at 650 GHz, and researchers are now working on multi-beam and sheet-beam devices capable of higher power than comparable low-voltage single round-beam units.

- The average power of submillimeter monolithic microwave integrated circuits and transistors climbed by a factor of five to eight, to the 100 mW level at 200 GHz and 1 mW at 650 GHz.

- The operating frequency range for milliwatt-class cryogenically cooled quantum cascade lasers was extended down to 1.8 THz in 2012, compared to 2.89 THz in 2007.

With an eye toward use outside the laboratory, researchers have been enhancing their sources in other ways,

too, including improved packaging for photonic devices and lasers and higher-temperature operation for quantum cascade lasers. Given the amount of effort and interest in the field, there will certainly be more advances and improvements to come. (For more on the current state of technology, I suggest consulting the *IEEE Transactions on Terahertz Science and Technology* and similar journals.)

That said, my main points still hold: While terahertz molecular spectroscopy has continuing scientific uses in radio astronomy and space remote sensing, some of the well-publicized mainstream proposals for terahertz technology continue to strain credulity. In addition, despite recent progress in cracking the terahertz nut, it is still exceedingly difficult to efficiently produce a useful level of power from a compact terahertz device. I strongly feel that any application touted as using terahertz radiation should be thoroughly validated and vetted against alternative approaches. Does it really use terahertz frequencies, or is some other portion of the electromagnetic spectrum involved? Is the application really practical, or does it require such rarefied conditions that it may never function reliably in the real world? Are there competing technologies that work just as well or better?

There is still a great deal that we don't know about working at terahertz frequencies. I do think we should keep vigorously pursuing the basic science and technology. For starters, we need to develop accurate and robust computational models for analyzing device design and operation at terahertz frequencies. Such models will be key to future advances in the field. We also need a better understanding of material properties at terahertz frequencies, as well as general terahertz phenomenology.

Ultimately, we may need to apply out-of-the-box thinking to create designs and approaches that marry new device physics with unconventional techniques. In other areas of electronics, we've overcome enormous challenges and beat improbable odds, and countless past predictions have been subsequently shattered by continued technological evolution. Of course, as with any emerging pursuit, Darwinian selection will have its say on the ultimate survivors. □

*NOTE: The views presented in this article are solely those of the author.*

**SOURCE SAMPLER:** Compact terahertz sources exhibit low power and conversion efficiencies of much less than 1 percent. And in nearly every case, as the frequency rises into the terahertz range, the source's output power plummets. Here, the  $Pf^2 = \text{constant}$  line is the power-frequency slope you'd expect to see in a more mature RF device, while the  $P\lambda = \text{constant}$  line is the expected slope for some commercial lasers.

# How I Quantified Myself

*Can self-measurement gadgets help us live healthier and better lives?*

ONE WARM NIGHT LAST FEBRUARY, I lay down to bed feeling like a lab mouse. A heat- and motion-sensing armband gauged my energy expenditure, another activity tracker clipped to my waistband recorded movement, a blood-pressure cuff connected to my iPad squeezed my right arm, and a brainwave-sensing headband would soon monitor my sleep. A scale linked by Bluetooth to an app on my iPad sat on the bathroom floor. With consistent use, these devices would provide a numeric picture of my general health and behaviors. They would give me intimate knowledge of my physical self, with all the information displayed neatly in graphs and charts.

Not too many years ago, you had to go to medical specialists to get this kind of biological data. Now, whether your problem is migraines or mood swings, you can keep track of your ailment with a consumer device that costs around US \$100. As these health- and-wellness gadgets proliferate, a “quantified self” movement is gaining strength: It’s attracting athletes, fitness buffs, data lovers, hypochondriacs, and people just trying to lose some weight.

by EMILY WALTZ

## Self-Quantifying Tools

Reporter Emily Waltz used the five gadgets shown here to record and analyze her biometric data

### 1 ZEO SLEEP MANAGER PRO: MOBILE \$100

A sensor headband measures electrical signals to track sleep stages and calculate "sleep quality." The customer uses a mobile app and online tools for sleep analysis.

### 2 FITBIT \$100

A small device with an accelerometer and altimeter, the Fitbit tracks motion, calculates calories burned, and displays real-time stats. The customer uses a mobile app or online tools to enter information about diet and to monitor progress toward goals.

### 4 iHEALTH BLOOD PRESSURE MONITORING SYSTEM \$100

The blood pressure cuff is attached to a dock, where the customer puts her iPhone or iPad to view data and monitor changes over time.

### 3 BODYMEDIA FIT CORE ARMBAND \$150

This armband uses an accelerometer and several skin sensors to track motion, skin temperature, and perspiration, producing a very accurate calculation of calories burned. The customer uses a mobile app or online program to enter information about diet and to monitor progress toward goals.

### 5 iHEALTH DIGITAL SCALE \$70

The scale uses Bluetooth to send weight data to a mobile app, where customers can set goals and track their progress.

average, whereas Fitbit came up with 2012. Knowing that BodyMedia is more accurate, I found myself using that data.

When I connected my BodyMedia armband to my computer through a USB cable, my stats popped up through the company's website. There's lots of information: a pie chart and four timelines that show energy burned per minute, vigorous activity versus moderate activity, steps per hour, and a crude estimation of sleep. BodyMedia's website tallies up your averages over days or weeks, and it keeps your history so you can look back through previous days. In a moment of geeky nostalgia, I clicked through my graphs for February and March and was able to spot the night I went to the symphony (a couple of hours with almost no movement). I also found the day I backed my car into my husband's—an event marked by my jumping out of the car and vigorously waving my arms (short spikes on the graph).

BodyMedia's meal-logging function allows you to input what you ate that day, and the program calculates your kilocalories consumed. But typing in the food information is painfully tedious and probably futile. "These devices do a good job measuring output, but not input," says James Hill, director of the Center for Human Nutrition at the University of Colorado. "Our research has shown that people are not within 60 percent of what they actually eat. It's not that people are lying. It's that it's very, very hard." BodyMedia has a database with thousands of foods, yet what I was looking for never seemed to be listed. So I would manually copy numbers from nutrition labels or input the weight of every raw ingredient in a meal in an attempt to get an accurate count.

After two months I had tons of data, but it was spread across three websites and three iPad apps. I needed a way to collect and analyze it all in one place. Health-management companies U.S. Preventive Medicine and Qualcomm Life have developed an app called Macaw that will do just that,

but it wasn't yet set up for my devices. So I did something low tech: I made a spreadsheet. I knew that exercise, alcohol, caffeine, big late dinners, and blood pressure are all linked to sleep quality, so I compared those numbers with each night of sleep data. Right away I ruled out blood pressure. The iHealth blood pressure monitor, which connects to an iPad or iPhone and stores your history through an app, said mine stayed low, around 102/65. That has been my blood pressure since long before my sleep problems developed.

In my spreadsheet, some correlations emerged. On days I did vigorous exercise like tennis or jogging, precious deep sleep increased 12 percent on average. Nights that I drank an alcoholic beverage or two, my time awake increased 48 percent and my REM sleep decreased 7 percent. And on nights when I ate more than my average number of kilocalories at dinner I was awake 51 percent more than usual—although that last figure is skewed by one particularly sleepless night.

IT'S KNOWN that feedback—seeing our own biological data in front of us—can affect our behavior. Several years ago David Levitsky, a nutritionist at Cornell, set up an experiment to see whether college freshmen could avoid the weight gain typical among first-year students. Levitsky separated students into two groups: one that weighed themselves every morning for 12 weeks and a control group that didn't. At the end of the 12 weeks, the students in the control group gained an average of 3 kg (7 pounds), but the students who weighed themselves every day collectively gained no weight. Feedback helped them dodge the dreaded freshman bulge.

Whether objective data can motivate people to make more dramatic lifestyle changes is unclear, say public health specialists. Joseph Kvedar, head of the Center for Connected Health at Harvard, is a proponent of health trackers. But he has found that only a small portion of the population, around

10 percent, will change their behavior based on tracker information alone. That 10 percent is composed of people inherently interested in data, like fitness buffs and "quantified selfers," the newly recognized class of nerdy people who revel in using technology to track their daily lives. Everyone else needs an additional motivator, he says, like coaching, social networking, games, or rewards.

Some device makers have picked up on that. Zeo offers a seven-step coaching program, and Fitbit offers an online community where you can compete with and trash talk your friends. Fitbiters have sorted themselves into groups like Walking at Work Treadmill Desk Users and my favorite: Crime Fighter Fitbit Users.

But even with these added motivators, the value of these devices to the general public remains unresolved. Hill at the University of Colorado, who is also cofounder of the National Weight Control Registry, says he has not seen any research suggesting that activity monitors like BodyMedia and Fitbit can help the average person lose weight. "We have to give people a reason to change and to exercise more and eat less, and I don't think information or data is enough," Hill says.

By the end of my experiment, I'd realized that mere data probably isn't enough to motivate me either. The stats made it clear that less alcohol and more exercise would improve my sleep. But lazing about the house with my husband, my son, and a glass of wine is my favorite thing to do, and I suspect that no amount of data will make me change my ways. Obsessing over my health data, however, was a much easier habit to kick. After two months of quantifying and analyzing, it felt blissful to unstrap all my monitors, forget about my daily stats, and just fall asleep. □

# Tapping the Power of 100 SUNS

CONCENTRATED SOLAR  
POWER WILL KEEP FUTURE  
ARMIES ON THE MARCH  
BY RICHARD STEVENSON  
ILLUSTRATION BY DANIEL HERTZBERG

napoleon's dictum no longer applies: These days, an army marches not so much on its stomach as on its batteries. Without them, soldiers can't see in the dark, work their radios, or determine their positions. But even the best storage batteries—accounting for one-fifth of the load in a typical infantryman's 45-kilogram pack—can't last the week or so that field soldiers require. The same problem is coming to afflict the rest of us, as we become ever more dependent on our smartphones and GPS navigation.

While we wait for better batteries we must find new ways to recharge the ones we have when we're far from a wall socket. What we need is a really good, portable photovoltaic system, one that can take in a huge gulp of sunlight and convert most of it into electricity. Such an advance could also help drive down the cost of solar electricity in sunny climes around the world and prevent great quantities of carbon emissions.

The most promising effort to create such superefficient photovoltaics began in 2005, when Doug Kirkpatrick, a veteran of the optics industry, kick-started the Very High Efficiency Solar Cell (VHESC) program for the U.S. Defense Advanced Research Projects Agency (DARPA). He wanted a way to build modules from solar cells that would convert a full 50 percent of the solar energy they receive into direct current. That's a jaw-dropping number when you consider that in 2005 the best laboratory devices were still shy of 40 percent efficiency and were improving by less than one percentage point per year.

KIRKPATRICK CONSIDERED the needs of the end user—the soldier. He noted that each electrical gizmo offered a different-size area for placing solar cells. This would make it possible to put more cells on bigger gadgets and use them to charge up other gizmos, such as flashlights, which have very little real estate. But that was a risky strategy, because the failure of one piece of equipment would put the others out of commission, too. Therefore, Kirkpatrick decreed that each piece of gear would have its own solar power, limiting the solar module's area to 10 square centimeters and setting cell efficiency at a minimum of 50 percent. The only other key specification for the module was power, which had to be at least 0.5 watts to recharge the batteries of the more common gadgets in an acceptable time.

The program started on the wrong foot by encouraging researchers to build on DARPA's existing programs to use biological processes to build solar cells. However, the agency abandoned that tack when two electrical engineers, then at the University of Delaware, wrote a white paper outlining a new way of using existing photovoltaic cells.

Christiana Honsberg, now at Arizona State University, and Allen Barnett, now at the University of New South Wales, in Australia, argued that the best approach would be to concentrate sunlight, break it into its constituent colors, and project each color onto the kind of solar cell best suited to it. This meant placing the cells side by side instead of the conventional way, in a vertical stack. Their paper went down very well, and DARPA invited the Delaware duo to a meeting where they could pitch their idea alongside 10 others. "A lot of people there were saying that we can't do 50 percent, but we could do 33 percent," says Kirkpatrick. "We were not interested."

Because the Delaware team wasn't banking on the success of a particular material but rather on a way of exploiting a diversity of materials, there could be many different paths to success. That

was another reason DARPA put Honsberg and Barnett in charge of VHESC, which has become one of the largest solar-energy research programs ever. Initially backed by US \$53 million, this effort, which commenced in September 2005, involves a consortium that at one point numbered 21 institutions, including BP Solar, Corning, and DuPont, and such universities as Georgia Tech, Harvard, MIT, Purdue, the University of California, Santa Barbara, and the University of Rochester.

**THERE'S NO BETTER** way to appreciate the merits of Honsberg and Barnett's approach than by considering how far short of the 50 percent target you fall using conventional tricks. It all comes down to an optimization problem, rather like that of a coffee-shop manager who has to decide how much to charge. If you set the price high, you make a good amount on each cup but sell few of them. If you set it low, you'll have a slim margin but a high volume. You need to find the sweet spot, the price that maximizes the product of the margin and the volume—that is, your profit. It's a similar story with solar cells, though here the variables are current and voltage, whose product, of course, is power.

At the heart of every photovoltaic cell is a pair of semiconductor layers. One layer has more negatively charged electrons than needed to form the material's crystalline bonds; thus it's known as *n*-type. The other, a *p*-type material, has a deficiency of such bond-forming electrons, creating what are known as holes. In a small region around which the layers meet—the *p-n* junction—the excess electrons move to fill in the deficiencies. This flow of electrons and holes leaves the *p*-type and *n*-type regions with negative and positive charges, respectively, creating an electric field.

When the cell absorbs photons, it creates pairs of electrons and holes. Then there is a net movement of holes in one direc-

tion and electrons in the other, due to both the electric field itself and to diffusion—the tendency of charge carriers to move to where their concentration is lower. An electric current is thus created in the circuit attached to the cell.

Solar-cell designers might be tempted to pick a semiconductor that best absorbs light of short wavelengths, like gallium nitride. Those photons carry the most energy and thus produce the highest voltage. Trouble is, there aren't many of them in sunlight, so the output current will be meager. Alternatively, designers can build cells from mercury cadmium telluride, a material that can absorb the solar spectrum all the way from the high-energy photons in the ultraviolet range to the low-energy photons in the short-wave infrared. Such a cell can indeed generate a lot of current, but its voltage—and hence its output power—is very low. So like the coffee-shop owner, solar-cell designers need to find a good compromise.

Theoretically, a semiconductor that absorbs light at infrared wavelengths greater than 910 nanometers will come closest to the sweet spot where power is maximized. Gallium arsenide fills the bill, and back in June 2005 researchers at Radboud University Nijmegen, in the Netherlands, were using this material to claim a single-cell efficiency record of 26.1 percent. Today, Alta Devices of Santa Clara, Calif., holds the record with a 28.2 percent cell. That's still a long way from Kirkpatrick's 50 percent target.

To close the gap requires a diversified strategy. Instead of using one material, a solar-cell maker can build cells from several. It's rather like offering coffee in three grades—a deluxe brand, a bargain brand, and a house brand—so as to hit profit-maximizing sweet spots for the rich customers, the poor ones, and everyone in between. The practical limit—for use in photocells, at least—is three different materials, given the traditional way of stacking them up.

To capture photons of relatively low energy, cell makers most often use a layer of germanium. For photons of intermediate energy, they include a gallium arsenide layer, and for high-energy photons, they create a third layer made up of indium gallium phosphide. The voltages simply add.

In theory, this strategy would work even better if you added more layers. But in practice, the material quality of the device tends to deteriorate, although some companies, such as Stanford University spin-off Solar Junction, have been working on approaches that promise to produce up to six stacked junctions.

The efficiency of triple-junction solar cells has been slowly creeping up. When the VHESC program kicked off in 2005, Spectrolab (a Boeing subsidiary in Sylmar, Calif.) led the way with a device boasting 32 percent efficiency, which the company had developed to power satellites. Now the Japanese firm Sharp holds the crown, with a device operating at 36.9 percent efficiency. It uses indium gallium arsenide, rather than germanium, for the bottom junction.

**THE OTHER BIG FACTOR** governing the financial success of any coffee shop is advertising. Good signage will pull in more traffic and should lead to more sales. In the case of solar cells, that means replacing a large triple-junction device with a lens or mirror that captures sunlight over

#### FUNNELING COLOR:

The DARPA design concentrates sunlight and splits it into "buckets" optimized to absorb at particular frequency ranges. The initial concept, not yet realized, was to split light into three ranges. High-energy photons would go to a single cell, while two or three cells stacked together would harness the power from mid-energy and low-energy cells, respectively. As of today, researchers have not been able to produce a good enough cell for the high-energy photons, so the prototype design has just two buckets—a "green" one for higher frequencies and a "red" one for lower ones.

ILLUSTRATION: JAMES PROVOST

an area just as great and focuses it on a photovoltaic chip that's much smaller and far cheaper to produce. Just as important as the reduction in cost is the increase in the efficiency and output power of the cell. When light is concentrated by a factor of 20, it doesn't merely create 20 times as many photons—it also boosts the output voltage, though it takes rather a bit of math to explain why this is the case.

In 2005, Spectrolab led the way with this approach, producing 39 percent efficiency with a triple-junction cell under the equivalent of the light coming from 236 suns. This bar has been raised many times. In 2011, Solar Junction claimed the most recent record of 43.5 percent cell efficiency at the equivalent of 400 suns, and this June, Sharp matched this figure with a cell operating at an undisclosed concentration.

To hit these figures, the cells must be mounted on systems that track the sun's position in the sky with tremendous precision. The smallest of such systems are several meters high and wide, which makes them suitable for solar farms but not as attachments to a soldier's gear. If concentration is to be used in portable solar systems, the factor of magnification must be far more modest.

**HIGH MAGNIFICATION:** Focusing sunlight on photovoltaic cells not only reduces the chip costs of the system but also boosts efficiency. That's because the more intense the light gets, the higher the voltage and the output power become. PHOTO: SOLFOCUS

Forty-three percent is pretty good, but it's not the desired 50. Further progress required a radically different approach, the one that Honsberg and Barnett had suggested to DARPA five years earlier. Rather than stack cells vertically, you tile them laterally, then split sunlight into several energy bands and focus each of them on different tiles.

Switching from a multijunction stack to a side-by-side array increases the maximum theoretical efficiency. That's because in a stacked system each layer is normally connected in series and thus has to produce the same amount of current. Designers can adjust layer thicknesses and other parameters to try to meet this requirement, but that's hard to do perfectly because the solar spectrum varies throughout the day—it's redder in the morning and late afternoon, bluer at midday. So a triple-junction cell's current is often limited to whatever the least productive layer can produce.

Also, stacked cells are limited by the way the stacks must be put together. To form these devices, crystalline layers are deposited atom by atom, and the spacing of the atoms in each layer must be very similar to avoid crystal imperfections. This limits

the number of material combinations—and therefore the range of absorption wavelengths—that can be used in a multijunction cell. By avoiding stacks, Honsberg and Barnett's approach allows materials with vastly different atomic spacing to be used alongside one another without any compromise in quality.

Calculations show that without concentrated sunlight, efficiency should rise from 51.5 to 55.6 percent when you shift from three junctions to four. And moving to five or six junctions should raise efficiency to 58 percent and 59.6 percent. Real-world gains would of course be lower, but still, upping the concentration should assure good results. Barnett and Honsberg estimate that for a six-junction cell operating at 20 suns you get an efficiency of 54.3 percent, and at 100 suns, 55.6 percent. With much more concentration than that the cell might overheat, and it would be difficult to point the mirrors precisely.

Barnett and his colleagues initially developed tracking-free solar modules using concentrations of 20 suns. A mobile user could manually point the cells toward the sun.

**ALTHOUGH IN THEORY** it should improve efficiency, splitting the solar spectrum into six portions and focusing each of them onto a separate cell is actually taking things too far, because substantial losses result from steering that many beams of light. "Ideally, we like to separate them into three 'buckets'—high energy, mid-energy, and low energy," explains Barnett. Each bucket contains up to three cells, which means it's also a stack, but one that isn't connected in series. That way, you don't have to worry about matching the current. Stacks are required because it's the only way to get to the five or six junctions you need to achieve 50 percent efficiency.

Deciding on the best way to get the sunlight into these buckets is tricky. At a meeting in 2006 at the University of Rochester, in New York, Kirkpatrick proposed to do it by using coatings that consist of finely built-up layers with different refractive indices that together create the desired interference patterns, much like those seen on the surface of a thin film of oil. Such dichroic designs let a range of wavelengths through while reflecting others with nearly perfect efficiency. This strategy would allow you to send the reflected light into one bucket and transmit light elsewhere, either onto cells or through another dichroic film for further spectral splitting. So far, designs have used only two buckets because the performance of the high-energy bucket isn't yet good enough to bother including it.

"Everybody was saying, 'No, no, no, that cannot work. You're wrong,'" Kirkpatrick says. The naysayers' skepticism reflected their background: They were aware only of incredibly precise dichroic coatings used in lasers. Kirkpatrick, however, knew that dichroics are also used in ceiling lamps in Europe to prevent filaments from overheating and thus failing prematurely.

Kirkpatrick demonstrated the capability of dichroic coatings by arranging for some of them to be made by Fiberstars (now Energy Focus) of Solon, Ohio. This firm joined the VHESC program shortly after the Rochester conference.

**THE INITIAL DESIGN** concept for the module—one that was never built—featured an optical element to split the sunlight into three spectral buckets and a lens the size of a thumbnail to focus it onto the low-energy, mid-energy, and high-energy cells. The modules were tiled, forming an array.

The choice for the mid-energy bucket was rather obvious: an indium gallium phosphide cell in front with a gallium arsenide cell behind. Together they captured wavelengths from the

**50 PERCENT, HO:** The efficiency of photovoltaic cells has continued to rise for decades, though particular designs may well have reached their practical limits. The highest efficiencies result from stacking three junctions on top of one another and using lenses or mirrors to concentrate the sunlight several hundredfold. ILLUSTRATION: JAMES PROVOST

near infrared to the green part of the spectrum, where the high-energy bucket began. But it was harder to fill the low-energy bucket, which stretched from the short infrared to the near infrared, and the high-energy bucket, which stretched from the green through the ultraviolet. Silicon works well in the infrared and can be partnered with germanium-based compounds, but it works even better when paired with indium gallium arsenide phosphide and indium gallium arsenide, because this combination generates some of its electricity at a higher voltage. There are very few good candidates for the high-energy bucket. Materials based on gallium nitride are the most promising, but they are dogged by problems such as dislocations in the crystal lattice.

Because of the difficulties with the high-energy bucket, the VHESC program has so far developed optical modules with merely low-energy cells, together with mid-energy variants that also capture some high-energy photons, although not as efficiently. In 2007, researchers measured the performance of cells made from indium gallium phosphide, gallium arsenide, silicon, indium gallium arsenide phosphide, and indium gallium arsenide, then calculated the contribution that each would deliver to a five-junction cell operating at 20 suns. They concluded that such a device could have a 42.9 percent efficiency, well ahead of the 40.7 percent record then held by a Spectrolab cell operating at a concentration of 240 suns.

Since then the program has defined its target differently, aiming not for a cell efficiency of 50 percent but rather for a module efficiency of 40 percent. This makes sense: Modules are always less efficient than cells, partly because imperfections prevent their optics from directing all the incident sunlight on the cell. And it's the output power of the modules that matters. The 40 percent target is still plenty tough, given that the best commercial triple-junction photovoltaic mod-

ules have efficiencies of just over 30 percent when operating at concentrations of several hundred suns.

By 2008 the consortium had set a new benchmark for efficiency with cells that collect light with one lens and then split the spectrum with a dichroic mirror onto tandem cells, one absorbing ultraviolet and visible light, the other absorbing infrared light. Operating at 20 suns, the device upped the record for module-wide efficiency from 32.6 percent to 36.7 percent when tested independently at the National Renewable Energy Laboratory (NREL). One hit 39.5 percent efficiency in tests at the University of Delaware. Differences in the values reflect disparities in the measurement of the aper-

ture above the focusing lens, misalignment of the cells, and variations in individual cells.

A road map to the 40 percent efficiency mark and beyond followed. Options include turning to more highly reflective coatings on the focusing lens; enshrouding the optics in silicone to reduce internal reflections; adding antireflection coatings to the individual cells; and improving the optical alignment of the module as a whole. The team recently implemented some of these ideas, increasing the efficiency of the modules measured at NREL to 38.5 percent.

"We moved away from silicon to hit the big number," admits Barnett, who is not a fan of records but acknowledges the good publicity they bring. More headline-grabbing success is now within reach, because Barnett believes that a recently fabricated, high-quality gallium phosphide cell could be inserted in front of the mirror, increasing module efficiency beyond 40 percent.

**FOR THE TIME BEING,** though, the researchers are concentrating less on efficiency and more on economics, trying to beat the cost per watt that all-silicon cells now provide. According to Dan Laubacher, a research fellow at DuPont, one of a handful of firms responsible for building the first prototype modules, costs can be trimmed by using silicon germanium cells for the low-energy bucket alongside cheaper dichroic coatings that sacrifice little in terms of performance.

The VHESC program is clearly on its way to providing a portable, affordable source of solar power. Soldiers will be the first to reap the benefits, but not the last. With such modules in hand, it'll be possible to carry the makings of a solar farm on a few trucks and set it up quickly. The result? A lot of electricity, with a relatively small footprint—not just for field soldiers but also for explorers, off-the-grid environmentalists, and isolated rural communities. It would shine wherever the sun does. □

# GENERATION SMART- PHONE

The smartphone's  
role as **constant  
companion,  
helper, coach,  
and guardian** has  
only just begun

BY  
**DAN  
SIEWIOREK**

**IT'S THE YEAR 2020** and newlyweds Tom and Sara are expecting their first child. Along with selecting the latest high-tech stroller, picking out a crib, and decorating the nursery, they download the “NewBorn” application suite to their universal communicator; they’re using what we’ll call a SmartPhone 20.0. Before the due date, they take the phone on a tour of the house, letting the phone’s sensors and machine-learning algorithms create light and sound “fingerprints” for each room.

When they settle Tom Jr. down for his first nap at home, they place the SmartPhone 20.0 in his crib. Understanding that the crib is where the baby sleeps, the SmartPhone activates its sudden infant death syndrome (SIDS) application and uses its built-in microphone, accelerometers, and other sensors to monitor little Tommy’s heartbeat and respiration. The “Baby Position” app analyzes the live video stream to ensure that Tommy does not flip over onto his stomach—a position that the medical journals still report contributes to SIDS. Of course, best practices in child rearing seem to change quickly, but Tom and Sara aren’t too worried about that because the NewBorn application suite updates itself with the latest medical findings. To lull Tommy to sleep, the SmartPhone 20.0 plays music, testing out a variety of selections and learning by observation which music is most soothing for this particular infant.

PHOTO: DAN SAELENGER; STYLIST: MARA-STEFANIA VAVYLOPOULOU

As a toddler, Tommy is very observant and has learned the combination on the gate to the swimming pool area. One day, while his parents have their backs turned, he starts working the lock. His SmartPhone “Guardian” app recognizes what he is doing, sounds an alarm, disables the lock, and plays a video demonstrating what could happen if Tommy fell into the pool with no one else around. Not happy at being thwarted, Tommy throws a tantrum, and the Guardian app, noting his parents’ arrival, briefs them on the situation and suggests a time-out.

**W**HILE THIS SCENARIO IS, of course, science fiction, many of the technologies I’m describing are here today in research labs or even in app stores. So the reality of a SmartPhone 20.0, along with its envisioned NewBorn suite, are not far off.

Geo-fencing, for example, is already a standard part of the iPhone operating system. Several smartphone apps can use GPS to identify the user’s location and bring up targeted advertising. Research focusing on improving location accuracy indoors, as well as software that “fingerprints” ambient light and sound, will soon make these apps able to accurately identify rooms in a house. Today, wearable SIDS monitors detect a baby’s breathing motion and vibrate when it stops, to stimulate the baby to take another breath—for example, the Halo, from the South African company Snuz. Researchers at the Technical University of Munich and others are testing emotion recognition from audio.

But the SmartPhone 20.0 won’t be just a high-tech baby monitor. Rather, the device or smart mobile devices like it will serve as nanny, nurse, or golf caddy—the perfect assistant for people of all ages. If you think that people can’t seem to make a move without consulting their phones today, well, you ain’t seen nothing yet.

Let’s age Tommy to 3 years old. Tom and Sara take him skiing for the first time. Tommy’s SmartPhone, now version 23.0, downloads the “Virtual Skiing Coach,” which uses accelerometers sewn into Tommy’s clothing to sense his posture and then offer suggestions for maintaining balance; when it foresees an impending collision, it quickly blurts out instructions on how to stop. We already have basic sensor-based virtual coaches. For example, the InForm Exercise Coach for knee osteoarthritis uses accelerometers and gyroscopes to track motion during rehabilitation exercises and correct errors. Such coaches would enable therapists to remotely monitor home-based exercise, making it easier for seniors to remain at home as they age and reducing health-care costs. These virtual coaches learn, so the longer people use them, the better they work.

At age 5, with the SmartPhone 25.0 education apps, Tommy has become a curious and eager learner. He looks forward to his first day at kindergarten. He meets Alice, who can neither hear nor speak, but because of her SmartPhone, she is able to easily participate in class. Alice greets Tommy by signing, and her SmartPhone plays a translation pro-

## A Lifetime of Apps

The smartphone of the future will be a constant companion, coach, collaborator, and advisor

**PERSONALIZED COACHING**, tips, and advice will be handed down from parent to child.

Drivers will allow their smartphones to **MONITOR THEIR DRIVING** and suggest routes that match their driving skills or personal preferences.

vided by the American Sign Language (ASL) app. Tommy responds, and Alice’s speech-recognition app provides her with real-time captioning. Tommy shares his favorite song with Alice, sending it from his SmartPhone to hers, which translates the music to vibrators in a vest she wears.

Back in 1997, Thad Starner of Georgia Tech put a camera in the bill of a baseball cap to enable a computer to interpret a user’s ASL gestures and display the results on a smartphone; no such product has yet been released commercially. But some ASL apps already exist: For example, the SmartSign from Georgia Tech, designed for hearing parents of deaf children, allows them to call up a video of a sign by speaking the

JAMES PROVOST

In the crib, the smartphone will **MONITOR** breathing and sleeping position.

Outside, the smartphone will **SET BOUNDARIES** through geo-fencing.

On the ski slope, the tennis court, and the golf course, the smartphone will be a **VIRTUAL COACH**.

As a **LANGUAGE TRANSLATOR**, the smartphone will be able to handle even sign languages.

**INDOOR MAPPING** of office buildings, malls, universities, and other complexes will be commonplace.

With a smartphone as an **ASSISTANT**, you'll never forget another name or face.

Teens will learn safer driving with a **SMARTPHONE ADVISOR**.

As a **VIRTUAL WATCHDOG**, the smartphone of the future will warn of potentially dangerous situations.

A smartphone-generated **VIDEO RECORD** of the day's events will help people remember them.

**HEALTH-MONITORING APPS** will prompt users to test themselves and send the results directly to doctors.

It will get easier to measure vital signs with **SMARTPHONE ATTACHMENTS**.

**ADVICE** will be passed down through generations—and kids will be able to turn to virtual grandparents for advice.

English word. The VibeAttire vest, which lets wearers feel music through vibrating motors sewn into the fabric, debuted at the 2010 International Consumer Electronics Show, or CES.

One day, Tommy is walking home from school, and the SmartPhone 27.0 Guardian app notices that a stranger has started a conversation with him and is coaxing Tommy to get into a van. The Guardian app whispers in Tommy's ear not to talk to the stranger and tells him to run to a nearby house, one the app has already verified as a local kid-safe house and confirmed that someone is home. The Guardian app takes a picture of the stranger and the license plate of his van and forwards the information to the police.

First Person Vision, introduced at the 2011 CES, uses video taken by wearable cameras and smartphones to identify gestures, actions, and faces in real time. It's not much of a stretch to envision it alerting users to threats.

**OR TOMMY'S 16TH BIRTHDAY**, his parents download the "Driving Instructor" app. Of course, by 2036 cars have many safety features but still require the driver to take over in emergency situations, so a driver's license is still required. Under the tutelage of the app, Tommy becomes an excellent driver; his parents trust that they'll be alerted if he starts driving recklessly.

These kinds of driver-monitoring tools are now in the lab. For example, the DriveCap project at the Quality of Life Technology Center, in Pittsburgh, run by Carnegie Mellon University and the University of Pittsburgh, uses in-car sensors to track driver behavior (accelerometers can detect erratic maneuvers and sudden changes in braking and acceleration) and the driver's cognitive load—that is, how attentive, tired, or overwhelmed the driver is—by focusing a camera on the eyes.

Years later, Tom Jr.'s SmartPhone (upgraded, of course, many times over the years) continues to be a trusted companion. On a business trip, the "Administrative Assistant" app reminds Tom of people's names and their connections to him; this is an easy-to-imagine extension of First Person Vision. Tom has an appointment in a large building complex, which has a confusing maze of corridors and bridges between buildings. Tom's SmartPhone snaps pictures for comparison to an archive of pictures of different parts of a building; that's something the First Person Vision app already does. By locating his position on a floor plan and knowing his destination, the "Building Navigation" app can efficiently guide him to his meeting. Applications like this already exist; the simplest are based on indoor maps developed by Google Places for Business.

On one trip, Tom twists his ankle while jogging. His SmartPhone directs him to the nearest emergency room; iPhone 4s users are already familiar with the Siri app's ability to do this kind of location finding. Later the SmartPhone recognizes that Tom is using his crutches incorrectly and gives him some pointers. While a "crutches coach" is not currently on the market, similar coaches have been demonstrated in the field. People who use manual wheelchairs are susceptible to repetitive-use injuries to their wrists and shoulder rotator cuffs. Researchers at Carnegie Mellon and the University of Pittsburgh have tested accelerometers in a wristwatch-like bracelet that classifies the arm movements and encourages those patterns that generate the least stress on the wrist and shoulder. Powered wheelchairs are being used to test more sophisticated built-in sensors to help users with spinal cord injuries avoid developing pressure sores by making sure they shift positions frequently; these devices have also been tested at the two Pittsburgh universities.

Tom wants to give his son, Thomas III, some of the tips he learned from his father on how to swing a baseball bat. So Tom uses a virtual coaching tool kit to develop his own baseball batting app. The app uses one set of sensors to recognize the type of pitch and another set, worn on the body, to analyze the batter's reaction. Tom doesn't stop there; he builds several coaching apps, including some for camping skills, gardening, household repairs, and automobile maintenance.

Tool kits already exist for simplifying the development of applications that augment reality—for example, the ARToolKit, an open-source project supported by the University of Washington; the University of Canterbury, in New Zealand; and ARToolworks, in Seattle. To pass along his father's life lessons, Tom records video of his father answering a variety of questions. In years to come, Tom's son will ask questions, which the SmartPhone's speech recognizer will match with an automatically generated index of the video clips, letting the grandson have simulated conversations with his grandfather.

Researchers at Carnegie Mellon have already used such synthetic interviews to enable people to converse with historic figures like Albert Einstein or Charles Darwin (played by actors) and with actual teenage breast-cancer survivors.

As Tom ages and his cognitive capacity decreases, he becomes less able to make critical decisions as he is driving. In particular, his decreased night vision makes it difficult to judge the speed of oncoming traffic. His SmartPhone "Driver Capability" app notices his hesitation and instructs the car's navigation system to use only intersections with left turn signals or to plan right-turn routes after dark. As Tom exhibits characteristics of early-onset Alzheimer's, he takes advantage of MemeXerciser, developed years ago in Pittsburgh, which collects snapshots and audio clips from a camera and microphone worn as a pendant. After an event, such as a trip to the zoo, with the aid of a video-editing tool kit, a caregiver can create an audio/video summary of the event, which Tom can replay at his leisure. Studies at Carnegie Mellon's Human-Computer Interaction Institute have demonstrated that MemeXerciser helps improve recall, not only of a particular event but also of activities that have not been recorded.

Even later, Tom's declining health requires ever more monitoring by his doctor. Fortunately, Tom's SmartPhone Health app allows his doctor to request routine self-monitoring tests using sensors built into the phone. The app administers these tests to Tom according to a schedule set by the doctor, who can review test results and order additional tests if necessary. The Health app also monitors Tom's activities and notifies the nurse in the independent living complex where he now resides if there are any anomalies.

Today, "health kiosks" that perform these functions are already in use in workplaces and senior living centers. United Healthcare, for example, offers them to its clients. It's not much of a stretch to imagine those functions moving to the smart-phone. Already, new applications like VitalClip, an iPhone accessory soon to go into a private beta test, allow users to measure vital signs by touching a finger to a sensor.

Tom's SmartPhone has captured his eventful life through video and audio, automatically divided into segments and indexed for textual search through speech-to-text conversions. Virtual coaches and synthetic interviews capture his hard-won wisdom and archive it for posterity. Later his son, and then his grandchildren, can tap that wisdom with Tom as one of his family's virtual companions, guardians, and coaches.

The apps that help Tom throughout his imaginary life are all straightforward extrapolations from what exists today. But technology isn't always bound to a straight path. In the future, the SmartPhone and smart communicators like it will decrease in size until sensing and computing is simply part of everyday objects, integrated into the outer "skins" of devices, woven into clothing, and embedded into countertops. This integrated technology will be situationally aware, understanding the user's intent and jumping in to help without a touch or a voice command. The Tommys of the future will be protected by helmets and uniforms that anticipate potential concussion-causing collisions and quickly react with counterforces that minimize bruising of the brain. Their footballs will signal "first down" from the bottom of the pile of players—no human judgment necessary. Their kitchens will figure out what meal is being made as ingredients are pulled from the refrigerator and step-by-step preparation instructions are displayed on the countertop. All this technology will have a zero carbon footprint, as it scavenges energy from radio waves in the environment and biodegrades when it is discarded. And we can see this future reflected in today's smartphones. □

## UNIVERSITY SPOTLIGHT

# Sun Yat-sen University / Carnegie Mellon University Joint Institute of Engineering

Sun Yat-sen University (SYSU) & Carnegie Mellon University (CMU) are partnering to establish the Joint Institute of Engineering (JI). SYSU and CMU are embarking on an exciting opportunity to transform engineering education in China. JI will provide world-class education and cutting-edge research in China's Pearl-River Delta region, which provides rapidly growing opportunities for future technology innovation.

JI is seeking **full-time faculty**, who have an interest in pursuing innovative, interdisciplinary education programs and in leading research efforts in all areas of Electrical/Computer Engineering. Candidates should possess a Ph.D. in ECE or related disciplines, with a demonstrated record and potential for research, teaching and leadership. The position includes an initial year on the Pittsburgh campus of CMU to establish educational and research collaborations before locating to **Guangzhou, China**.

This is a **worldwide search** open to qualified candidates from all countries and of all nationalities, with an internationally competitive compensation package for all qualified candidates.

## Faculty Positions Available in Electrical/Computer Engineering

Visit <http://sysucmuji.sysu.edu.cn> or <http://sysucmuji.cmu.edu> for details.

### Georgia Tech School of Electrical and Computer Engineering

#### Hightower Chair

#### School of Electrical and Computer Engineering Georgia Institute of Technology

**Endowed Chair:** The Georgia Institute of Technology announces the Hightower Chair in the School of Electrical and Computer Engineering (ECE). Applications and nominations for this endowed chair are now being accepted. This Chair is associated with the discipline of systems and control. Candidates are expected to have a distinguished record of performance broadly related to systems and control and its interdisciplinary application, as well as a demonstrated potential for leadership in research and education. The Chair holder will be expected to establish a high-impact research program funded by industry and government, draw outstanding students to the program, and serve as a mentor to other faculty. The academic salary for the Chair holder will be paid from Institute funds, enabling funds generated by the endowment to be used by the Chair holder for the purposes of research support and program development. Salary will be fully competitive. Applications and nominations should be submitted to:

Hightower Chair Search Committee,  
c/o Toya Jordan, School of Electrical and Computer Engineering.  
Georgia Institute of Technology,  
Atlanta, Georgia 30332-0250 or by email to [toya.jordan@ece.gatech.edu](mailto:toya.jordan@ece.gatech.edu).

Interested parties are encouraged to submit their materials no later than **October 31, 2012** to assure optimal consideration.

The Georgia Institute of Technology is an Equal Opportunity/Affirmative Action employer.

### Faculty Positions

**Department:**  
**Electrical Engineering**

**Location:**  
**Abu Dhabi, United Arab Emirates**

#### Description:

The Electrical Engineering Department at The Petroleum Institute in Abu Dhabi, United Arab Emirates, is inviting applications for two full-time faculty positions, one in the area of **Instrumentation** and the other in the area of **Power System Protection**. Both positions are open for all faculty ranks.

#### Position Description:

Successful candidates are expected to

- teach undergraduate/graduate courses,
- supervise undergraduate/graduate students,
- engage in appropriate levels of service to the institute and the profession,
- initiate/conduct research activities and attract funding,
- Disseminate research results in high-profile publications in their respective fields of expertise.

**Qualifications:** Candidates must have an earned Ph.D. degree in Electrical Engineering, or in a closely related discipline, from an accredited university, and possess an excellent and demonstrated teaching and research expertise in the sought specialties mentioned above.

**Salary/Benefits:** The total compensation package includes a tax-free 12-month base salary, and a benefits allowance that covers relocation, housing, initial furnishings, utilities; transportation (interest-free automobile purchase loan), health insurance, end-of-service benefit and annual leave travel. Applicants will be required to pass a pre-employment health examination.

**To Apply:** Interested candidates should submit online (<https://career.pi.ac.ae>) a letter of interest and a detailed resume listing qualifications and experience. The closing date is **December 15th, 2012**. Only shortlisted applicants will be notified.

## UNIVERSITY SPOTLIGHT

School of Electrical  
& Computer Engineering  
College of Engineering

## The University of Oklahoma Faculty Positions in Medical Imaging

**Positions Available.** The University of Oklahoma, College of Engineering, through its partnership with the University of Oklahoma Cancer Center invites applications and nominations for two tenure-track faculty positions at all academic levels in the area of medical imaging. All areas of medical imaging will be considered, although particular emphasis will be placed on x-ray cancer imaging and optical genetic cancer imaging. This is an interdisciplinary cluster hire. The successful candidate will have opportunity to join the faculty of one of the academic units within the College of Engineering, based on the mutual interests of the candidate and the unit. Adjunct faculty appointment in the College of Medicine and affiliation with the University of Oklahoma Biomedical Engineering Center is also possible.

**Candidate Qualifications.** Successful candidates will be visionary, collegial and highly motivated leaders in their field, who thrive both as individual researchers and as members of dynamic groups. A Ph.D. in Engineering, Physics, Medical Physics, or other related fields is required. In addition, an established vibrant research program with a track record of external grants, especially NIH/NCI sponsorship, or the potential to quickly create such a program based upon demonstrated experiences working in academia, government or industry, is an important requirement. Successful candidates will be expected to have a commitment to graduate and undergraduate education as well.

**The University of Oklahoma.** Established in 1890, the University of Oklahoma is a comprehensive public research university offering a wide array of undergraduate, graduate and professional programs and extensive continuing education and public service programs. Its 2000 acre Norman Campus houses 15 colleges with approximately 1300 faculty serving more than 26,000 students. The new 277 acre adjacent Research Campus houses more than 750,000 square feet among nine buildings constructed since 2003, including the National Weather Center, Stephenson Research and Technology Center, Stephenson Life Sciences Research Center, and several Partners Place buildings that co-locate University offices with more than 350 private sector employees across more than a dozen companies. Two additional Partners Place buildings are underway.

**Application Process.** Confidential review of nominations, indications of interest and applications will begin June 1, 2012 and continue until all positions are filled. Candidates are invited to submit a letter of interest describing their research vision and demonstrating how they fulfill the qualifications noted above, a detailed curriculum vita, and the names of three references who will be contacted only upon approval from the applicant. Minorities and women are encouraged to apply. Electronic submission in PDF format is preferred, and all application information and inquiries should be directed to the search committee chair:

Dr. James Sluss, Director  
School of Electrical and Computer Engineering  
110 W. Boyd St., Rm. 150  
Norman, OK 73019-1102  
Voice: 405.325.8131  
Fax: 405.325.7066  
E-mail: [eceseach@ou.edu](mailto:eceseach@ou.edu)

The University of Oklahoma is an Equal Opportunity institution. [www.ou.edu/eoo](http://www.ou.edu/eoo)

## Toyota Technological Institute

has openings for tenured- or tenure-track associate professor positions in the Department of Advanced Science and Technology, Faculty of Engineering.

For more information, please refer to the website

[http://www.toyota-ti.ac.jp/bosyu/index\\_E.html](http://www.toyota-ti.ac.jp/bosyu/index_E.html)

### Research fields

#### 1. Computational intelligence and intelligent information processing

including machine learning, data mining, computer vision, image understanding, and intelligent human-machine interface, etc.

#### 2. Electrical energy

including power electronics, electric power conversion and electrical machinery and apparatus, etc.

#### 3. Mechatronics

including computer-aided manufacturing engineering, intelligent mechanical systems and biomimetics, etc.

**Start date:** April 2013 or at the earliest convenience

**Documents:** (1) A curriculum vitae  
(2) A list of publications  
(3) Copies of 5 representative papers  
(4) A brief summary and future plan of your research and educational statement (within three pages each)  
(5) Names of two references including phone numbers and e-mail addresses  
(6) An application form (available on our website)

**Deadline:** October 31, 2012

### Inquiries:

#### 1. Computational intelligence and intelligent information processing

Search Committee Chair  
Professor Tatsuo Narikiyo  
(Phone) +81-52-809-1816  
(E-mail) [n-tatsuo@toyota-ti.ac.jp](mailto:n-tatsuo@toyota-ti.ac.jp)

#### 2. Electrical energy and 3. Mechatronics

Search Committee Chair  
Professor Shuji Tanaka  
(Phone) +81-52-809-1775  
(E-mail) [tanaka\\_mat@toyota-ti.ac.jp](mailto:tanaka_mat@toyota-ti.ac.jp)

The above documentation should be sent to:

Mr. Takashi Hirato  
Toyota Technological Institute  
2-12-1, Hisakata, Tempaku-ku  
Nagoya, 468-8511 Japan

Please write "Application for (fill in the research field you would like to apply)" in red on the return envelope.

## Dean College of Engineering

Rowan University is seeking an innovative leader for the position of Dean of the College of Engineering. Located in New Jersey, Rowan is a comprehensive public institution with over 11,000 undergraduate and graduate students enrolled in nine colleges, including the new Cooper Medical School. The recent State designation of Rowan as a *research university* has set the framework for new multidisciplinary research opportunities and the creation of new advanced degree programs.

The College of Engineering, created following a \$100M gift by Henry and Betty Rowan in 1992, enrolls over 600 students in four departments. *U.S. News & World Report* consistently ranks the College and its programs among the nation's best for undergraduate engineering. Further information is available at

[www.rowan.edu/colleges/engineering](http://www.rowan.edu/colleges/engineering)

As the College's chief academic officer, the new Dean will be responsible for providing overall leadership to promote excellence and advance its national and international standing in research, and undergraduate and graduate education. Specific responsibilities will include fundraising, budget management, alumni relations, and outreach.

The qualifications include a PhD in engineering or related field; an established record of teaching, scholarship, and service appropriate to appointment to full professor; and experience and demonstrated success as a leader in academic administration, fundraising, budget and personnel management.

Review of applications will start immediately. Applications submitted after December 15, 2012 may not receive consideration. Candidates should submit a letter of interest including a vision statement, current vita, and names for three references to [engdeansearch@rowan.edu](mailto:engdeansearch@rowan.edu).

Rowan is an equal opportunity employer, and encourages members of diverse groups to apply.

**Aalto University**  
School of Electrical  
Engineering

### *Smart power. Novel networks.*

**Aalto University** School of Electrical Engineering transforms scientific and technological research results to advanced solutions and applications ranging from nanotechnology to space robotics.

## SEVEN Tenure Track or Tenured PROFESSOR Positions

Aalto University School of Electrical Engineering seeks experts especially in the following fields:

- Electrical Engineering (power and energy), Automatic Control, Embedded Systems, Smart Living Environment;
- Radio Science and Engineering, Radio Astronomy, Space Science and Engineering, Optoelectronics;
- Communications Engineering and Networking Technology.

The positions are open at all levels from assistant professor to full tenured professor.

Applicants must have a doctoral degree in a relevant field. For assistant and associate professor levels evaluation focuses on merits and potential for excellence, for full professors we look for demonstrated excellence in research and teaching. Relevant industrial experience is appreciated.

Application deadline is September 30, 2012. For further information and application details, please visit at:  
[www.elec.aalto.fi/tenuretrack](http://www.elec.aalto.fi/tenuretrack)

Aalto University is a new university with over a century of experience. Created from a high-profile merger between three leading universities in Finland – the Helsinki School of Economics, the Helsinki University of Technology and the University of Art and Design Helsinki – Aalto University opens up new possibilities for strong multi-disciplinary education and research. The university's ambitious goal is to rank among the top universities in the world in its areas of specialization. At Aalto University, there are 20 000 students and a staff of 5 000, of which 350 are professors.

[aalto.fi](http://aalto.fi)

# SRM UNIVERSITY

## CHENNAI, INDIA

SRM University, is part of four decade old SRM Group of Educational Institutions. The University offers Undergraduate, Postgraduate, Doctoral and Post-Doctoral programs in Engineering, Architecture, Dentistry, Medicine, Allied Health Sciences and Science & Humanities. There are approximately 28000 students and 2400 Faculty and Staff members. SRM Engineering College, constituent of the SRM University, has been accredited by Indian National Board of Accreditation- AICTE- with an "A" grade. It is also an ISO 9002 certified institution. The Electronics & Communications Engineering program at SRM University has been accredited by USA based **Accreditation Board for Engineering and Technology, Inc. (ABET)**. The University is in the process of getting ABET accreditation for other engineering disciplines also.

The University through the SRM Research Foundation has fostered research in its various programs. The Faculty Members are highly encouraged to conduct research in their respective field. Outstanding research works are recognized by the University management and individuals are rewarded for their work.

SRM University is in the process of expanding the Faculty in every field of Engineering, Medicine, Management and Science. We are inviting applications from qualified candidates for the position of Professor, Associate Professor, Assistant Professor, Research Associate and Post-Doctoral Fellows. All these positions are open to International Academia, Indian and Non-Resident Indians (NRI). Suitable work visa will be arranged by the University wherever necessary. The selected candidates should be willing to relocate to Chennai, India preferably for at least 2-3 years. We also invite candidates who are on sabbatical, for teaching courses and conducting research for one semester. The prospective applicants may visit our website: [www.srmuniv.ac.in](http://www.srmuniv.ac.in).

#### Eligibility Criteria:

- **Professor** : Ph.D. with at least 10 years of academic/industry experience with demonstrated excellence in Research and Teaching.
- **Associate Professor** : Ph.D. with at least 5 years of academic/industry experience with demonstrated excellence in Research and Teaching.
- **Assistant Professor** : Ph.D. with at least 3 years of academic/industry experience with demonstrated excellence in Research and Teaching.
- **Research Associate** : Ph.D. with at least one year of demonstrated research experience.
- **Post-Doctoral Fellow** : Ph.D.

Compensation package will include competitive salary and full benefits (Medical, Dental, Paid Leave, Travel allowance etc.)

Interested candidates are requested to send their latest CV to: [hrd@srmuniv.ac.in](mailto:hrd@srmuniv.ac.in)

Please include in the correspondence the salary expectation and the required lead time for joining.

**The Registrar, SRM University**, SRM Nagar, Kattankulathur – 603203.

Kancheepuram Dist, Chennai Area. Tamil Nadu, India. **E-mail:** [hrd@srmuniv.ac.in](mailto:hrd@srmuniv.ac.in)

Advanced projects  
for tomorrow?

Yes!!!

Yes, together we will build the future. Alstom is a global leader in the world of power generation, power transmission and rail infrastructure and sets the benchmark for innovative and environmentally friendly technologies. Alstom builds the fastest train and the highest capacity automated metro in the world, provides turnkey integrated power plant solutions and associated services for a wide variety of energy sources, including hydro, nuclear, gas, coal and wind, and it offers a wide range of solutions for power transmission, with a focus on smart grids. The Group employs 92,600 people in around 100 countries, and had sales of € 21.7 billion in 2011/12.

## Senior Power System Studies Engineer Gas Plant Products

We are looking for a Senior Electrical Engineer with specialist knowledge in power system design to strengthen our Power System Studies team in **Baden, Switzerland**.

**Your tasks:** Primarily focus on project execution and support the development of new gas plant products - Assume responsibility for specifying and carrying out all power system dynamic studies that are required to fulfill contract and grid code requirements - Discuss technical issues with the client and/or grid authority to resolve problems encountered during project execution related to the scope of your work - Provide the necessary technical expertise within the scope of electrical engineering for the development of new products - Develop control system models and validate these models with field measurements

**Your profile:** University degree (Master's or higher) in electrical engineering with emphasis on power systems, electrical machinery and control systems - At least two years of experience in performing power system computations such as load flow, short-circuit, harmonic analysis and in particular in the area of dynamic and electromagnetic transient simulations - Experience in simulating control systems with focus on generator excitation and turbine controls - Know-how in applying dynamic simulation tools such as PSS/E, MATLAB Simulink, ATP/EMTP, etc. - Know-how in developing models of control systems and their implementation in a high-level programming language such as FORTRAN highly desirable - Practical experience in the area of validation of simulation models with field measurements and/or working experience in a power system studies environment advantageous - Any experience in the area of control systems beneficial - Confident team player with high degree of self-motivation - Excellent analytical and communication skills - Interest in acquiring new technology skills - English language skills essential; in addition, German skills would be an advantage - Intercultural competence

ALSTOM (Switzerland) Ltd, Sandra Wiederkehr, Human Resources, phone: +41 (0)56 205 28 43

We look forward to receiving your application (Job Number **BAD001BR**) via:

## WE'LL GIVE YOU PLENTY OF SPACE TO SPREAD YOUR WINGS

We're looking for people who don't compromise their freedom. People who test the limits and think outside the box. Those interested in revolutionary research of nanotechnology are constantly exploring new paths. There is plenty of space to do just that at imec. Thanks to our training programs you can develop your talents to the fullest. Come and join us and we'll give you plenty of space to spread your wings.

We are looking for:

- STT MRAM Device Engineer
- Research Scientist to Develop IC Design Flows for Rapid Technology Assessment
- Analog Circuit Designers

**NXP Semiconductors N.V.** (NASDAQ: NXPI) provides High Performance Mixed Signal and Standard Product solutions that leverage its leading RF, Analog, Power Management, Interface, Security, Digital Processing and Manufacturing expertise. These innovations are used in a wide range of automotive, industrial, consumer, lighting, medical, computing and identification applications. A global semiconductor company with operations in more than 25 countries, NXP posted revenue of USD 4.4 billion in 2010.

Within our Regional Quality Centre in Nijmegen we are looking for a:

<b>Electrical Failure Analyses Engineer</b>	(NXP Job ID 8997)
<b>Group Leader Failure Analyses</b>	(NXP Job ID 8991)
<b>Senior Engineer FIB Circuit Edit</b>	(NXP Job ID 9002)
<b>Principal Engineer Reliability Physics</b>	(NXP Job ID 8745)

## The Global Brain Trade

A survey reveals the worldwide migration patterns of researchers

**W**HICH countries have the most foreign scientists, and which ones suffer from the worst brain drain? To answer these questions, researchers at the National Bureau of Economic Research, in Massachusetts, conducted a Web-based survey of over 17 000 published scientists in 16 countries. (China wasn't surveyed: The researchers tried but were unsuccessful in administering the survey to scientists there.) While the United States is, unsurprisingly, a popular destination for scientists from around the world, Switzerland actually has the highest percentage of immigrant scientists. On the other side of the coin, Japan is the most insular country surveyed, exchanging relatively little scientific talent with the rest of the world.

—Ritchie S. King

## Instant Access to IEEE Publications

Enhance your IEEE print subscription with online access to the IEEE *Xplore*® digital library.

- Download papers the day they are published
- Discover related content in IEEE *Xplore*
- Significant savings over print with an online institutional subscription

Start today to maximize your research potential.
